NCSA Contacts

Mail user feedback, bug reports, and questions to:

NCSA Scientific Data Technologies HDF Group 152 Computing Applications Bldg. 605 E. Springfield Ave. Champaign, IL 61820-5518

Send electronic correspondence and bug reports to the following:

hdfhelp@ncsa.uiuc.edu

Internet access

HDF is available without charge from NCSA's anonymous FTP server:

ftp.ncsa.uiuc.edu/HDF/HDF/

It is also accessible through the HDF Group's World Wide Web home page:

http://hdf.ncsa.uiuc.edu/

Section 1

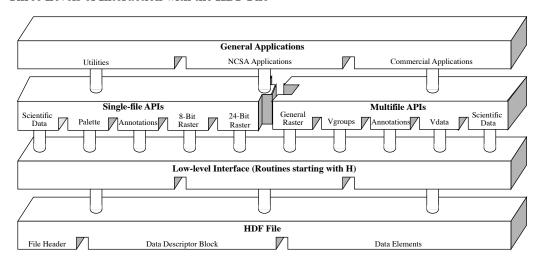

Introduction to the HDF APIs

1.1 Overview of the HDF Interfaces

The HDF library structure consists of two interface layers and one application layer built upon a physical file format. (See Figure 1a.) The first layer, or the *low-level interface*, is generally reserved for software developers because it provides support for low-level details such as file I/O, error handling, and memory management. The second layer, containing the single and multifile *application interfaces*, consists of a set of interfaces designed to simplify the process of storing and accessing data. The single-file interfaces operate on one file at a time, whereas the multifile interfaces can operate on several files simultaneously. The highest HDF layer includes various NCSA and commercial applications and a collection of command-line utilities that operate on HDF files or the data objects they contain.

FIGURE 1a

Three Levels of Interaction with the HDF File

1.2 Low-Level Interface

This is the layer of HDF reserved for software developers and provides routines for error handling, file I/O, memory management, and physical storage. These routines are prefaced with 'H'. For a more detailed discussion of the low-level interface, consult the HDF Specifications and Developer's Guide from the HDF WWW home page at http://hdf.ncsa.uiuc.edu/.

The low-level interface provides a collection of routines that are prefaced with either 'H', 'HE', or 'HX'. The H routines are for managing HDF files. The HE routines provide error handlings. The HX routines are for managing HDF external files.

Prior to HDF version 3.2, all low-level routines began with the prefix 'DF'. As of HDF version 3.3, the DF interface was no longer recommended for use. It is only supported to maintain backward compatibility with programs and files created under earlier versions of the HDF library.

1.3 Multifile Application Interfaces

The HDF multifile interfaces are designed to allow operations on more than one file and more than one data object at the same time. The multifile interfaces provided are AN, GR, SD, VS, VSQ, VF, V, and VH. The AN interface is the multifile version of the DFAN annotation interface. The GR interface is the multifile version of the 8- and 24-bit raster image interfaces. The SD interface is the multifile version of the scientific data set interface. The VS, VSQ, and VF interfaces support the vdata model. The V and VH interfaces provide support for the vgroup data model.

Like the single-file interfaces, the multifile interfaces are built upon the low-level H routines. Unlike single-file operations, operations performed via a multifile interface are not implicitly preceded by **Hopen** and followed by **Hclose**. Instead, each series of operations on a file must be preceded by an explicit call to open and close the file. Once the file is opened, it remains open until an explicit call is made to close it. This process allows operations on more than one file at a time.

1.3.1 Scientific Data Sets: SD Interface

The scientific data set interface provides a collection of routines for reading and writing arrays of data. Multidimensional arrays accompanied by a record of their dimension and number type are called scientific data sets. Under the multifile interface, scientific data sets may include predefined or user defined attribute records. Each attribute record is optional and describes a particular facet of the environment from which the scientific data was taken.

The names of the routines in the multifile scientific data set interface are prefaced by 'SD'. The equivalent FORTRAN-77 routine names are prefaced by 'sf'.

1.3.2 Annotations: AN Interface

The purpose of the AN multifile annotation interface is to permit concurrent operations on a set of annotations that exist in more than one file. Annotations consist of labels and descriptions.

The C routine names of the multifile annotation interface are prefaced by the string 'AN' and the FORTRAN-77 routine names are prefaced by 'af'.

1.3.3 General Raster Images: GR Interface

The routines in the GR interface provide multifile operations on general raster image data sets.

The C routine names in the general raster interface have the prefix 'GR' and the equivalent FOR-TRAN-77 routine names are prefaced by 'mg'.

1.3.4 Scientific Data Sets: netCDF Interface

The SD interface is designed to be as compatible as possible with netCDF, an interface developed by the Unidata Program Center. Consequently, the SD interface can read files written by the netCDF interface, and the netCDF interface (as implemented in HDF) can read both netCDF files and HDF files that contain scientific data sets.

Further information regarding the netCDF interface routines and their equivalents in the HDF interface can be found in the HDF User's Guide. Additional information on the netCDF interface can be found in the netCDF User's Guide available by anonymous ftp from unidata.ucar.edu.

1.3.5 Vdata: The VS Interface

The VS interface provides a collection of routines for reading and writing customized tables. Each table is comprised of a series of records whose values are stored in fixed length fields. In addition to its records, a vdata may contain four kinds of identifying information: a name, class, data type and a number of field names.

Routines in the VS interface are prefaced by 'VS'. The equivalent FORTRAN-77 routine names are prefaced by 'vsf'.

1.3.6 Vdata Query: VSQ Interface

The VSQ interface provides a collection of routines for inquiring about existing vdata. These routines provide information such as the number of records in a vdata, its field names, number types, and name. All routines in the VSQ interface are prefaced by 'VSQ'. The equivalent FORTRAN-77 routine names are prefaced by 'vsq'.

1.3.7 Vdata Fields: VF Interface

The VF interface provides a collection of routines for inquiring about the fields in an existing vdata. These routines provide information such as the field name, size, order, and number type.

All routines in the VF interface are prefaced by 'VF'. There are no equivalent FORTRAN-77 functions.

1.3.8 Vgroups: V Interface

The vgroup interface provides a collection of routines for grouping and manipulating HDF data objects in the file. Each vgroup may contain one or more vdatas, vgroups, or other HDF data objects. In addition to its members, a vgroup may also be given a name and a class.

Every routine name in the vgroup interface are prefaced by 'V'. The equivalent FORTRAN-77 routine names are prefaced by 'vf'.

1.3.9 Vdata/Vgroups: VH Interface

The high-level VH interface provides a collection of routines for creating simple vdatas and vgroups with a single function call. All routines in this interface are prefaced by 'VH'. The equivalent FORTRAN-77 routine names are prefaced by 'vh'.

1.3.10 Vgroup Inquiry: VQ Interface

The high-level VQ interface provides one routine that returns tag information from a specified vgroup, and one routine that returns reference number information from a specified vgroup. All C routine names in this interface are prefaced by 'VQ'. The equivalent Fortran-77 routine names are prefaced by 'vq'.

1.4 Single-File Application Interfaces

The HDF single-file application interfaces include several independent modules each is designed to simplify the process of storing and accessing a specific type of data. These interfaces support the 8-bit raster image(DFR8), 24-bit raster image (DF24), palette (DFP), scientific data (DFSD), and annotation (DFAN) models. All single-file interfaces are built upon the H routines - unless otherwise specified, all the low-level details can be ignored.

1.4.1 24-bit Raster Image Sets: DF24 Interface

The HDF 24-bit raster interface provides a collection of routines for managing 24-bit raster image sets. A 24-bit raster image set is comprised of a 24-bit raster image array and its accompanied dimension record. Raster image sets may also include a palette.

The names of the routines in the 24-bit raster interface are prefaced by 'DF24'. The equivalent FORTRAN-77 routine names are prefaced by 'd2'.

1.4.2 8-bit Raster Image Sets: DFR8 Interface

The HDF 8-bit raster interface provides a collection of routines for managing 8-bit raster image sets. An 8-bit raster image set is comprised of an 8-bit raster image array and its accompanied dimension record. Raster image sets may also include a palette.

Every function in the 8-bit raster interface begins with the prefix 'DFR8'. The equivalent FOR-TRAN-77 functions use the prefix 'd8'.

1.4.3 Palettes: DFP Interface

The HDF palette interface provides a collection of routines for managing palette data. This interface is most often used for working with multiple palettes stored in a single file or palettes not specifically assigned to a raster image.

The names of the routines in the palette interface are prefaced by 'DFP'. The equivalent FOR-TRAN-77 routine names are prefaced by 'dp'.

1.4.4 Scientific Data Sets: DFSD Interface

There are two HDF interfaces that support multidimensional arrays: the single-file DFSD interface described here, which permits access to only one file at a time, and the newer multifile SD interface, which permits simultaneous access to more than one file. The existence of the single-file scientific data set interface is simply to support backward compatibility for previously created files and applications. It is recommended that the multifile scientific data set interface is to be used where possible.

The single-file scientific data set interface provides a collection of routines for reading and writing arrays of data. A scientific data set is comprised of a scientific data array and its accompanied rank, name and number type. Scientific data sets may also include predefined attribute records.

The names of the routines in the single-file scientific data set interface are prefaced by 'DFSD'. The equivalent FORTRAN-77 routine names are prefaced by 'ds'.

1.4.5 Annotations: DFAN Interface

The single-file annotation interface provides a collection of routines for reading and writing text strings assigned to HDF data objects or files. Annotations consist of labels and descriptions.

The names of the routines in the single-file annotation interface are prefaced by 'DFAN'. The equivalent FORTRAN-77 routine names are prefaced by 'da'.

1.5 FORTRAN-77 and C Language Issues

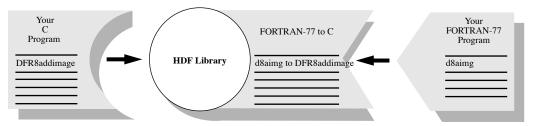

In order to make the FORTRAN-77 and C versions of each routine as similar as possible, some compromises have been made in the process of simplifying the interface for both programming languages.

1.5.1 FORTRAN-77-to-C Translation

Nearly all of the HDF library code is written in C. The Fortran HDF API routines translate all parameter data types to C data types, then call the C routine that performs the main function. For example, **d8aimg** is the FORTRAN-77 equivalent for **DFR8addimage**. Calls to either routine execute the same C code that adds an 8-bit raster image to an HDF file - see the following figure.

FIGURE 1b

Use of a Function Call Converter to Route FORTRAN-77 HDF Calls to the C Library

1.5.2 Case Sensitivity

FORTRAN-77 identifiers generally are not case sensitive, whereas C identifiers are. Although all of the FORTRAN-77 routines shown in this manual are written in lower case, FORTRAN-77 programs can generally call them using either upper- or lower-case letters without loss of meaning.

1.5.3 Name Length

Because some FORTRAN-77 compilers only interpret identifier names with seven or fewer characters, the first seven characters of the FORTRAN-77 HDF routine names are unique.

1.5.4 Header Files

The inclusion of header files is not generally permitted by FORTRAN-77 compilers. However, it is sometimes available as an option. On UNIX systems, for example, the macro processors m4 and cpp let the compiler include and preprocess header files. If this capability is not available, the user may have to copy the declarations, definitions, and values needed from the files dffunc.inc and hdf.inc into the user application. If the capability is available, the files can be included in the Fortran code. The files reside in the include/ subdirectory of the directory where the HDF library is installed on the user's system.

1.5.5 Data Type Specifications

When mixing machines, compilers, and languages, it is difficult to maintain consistent data type definitions. For instance, on some machines an integer is a 32-bit quantity and on others, a 16-bit quantity. In addition, the differences between FORTRAN-77 and C lead to difficulties in describing the data types found in the argument lists of HDF routines. To maintain portability, the HDF library expects assigned names for all data types used in HDF routines. (See Table 1A.)

TABLE 1A

Data Type Definitions

Definition Name	Definition Value	Description
DFNT_CHAR8	4	8-bit character type
DFNT_CHAR	4	Same as DFNT_CHAR8
DFNT_UCHAR8	3	8-bit unsigned character type
DFNT_UCHAR	3	Same as DFNT_UCHAR8
DFNT_INT8	20	8-bit integer type
DFNT_UINT8	21	8-bit unsigned integer type
DFNT_INT16	22	16-bit integer type
DFNT_UINT16	23	16-bit unsigned integer type
DFNT_INT32	24	32-bit integer type
DFNT_UINT32	25	32-bit unsigned integer type
DFNT_FLOAT32	5	32-bit floating-point type
DFNT_FLOAT64	6	64-bit floating-point type
DFNT_NINT8	(DFNT_NATIVE DFNT_INT8)	8-bit native integer type
DFNT_NUINT8	(DFNT_NATIVE DFNT_UINT8)	8-bit native unsigned integer type
DFNT_NINT16	(DFNT_NATIVE DFNT_INT16)	16-bit native integer type
DFNT_NUINT16	(DFNT_NATIVE DFNT_UINT16)	16-bit native unsigned integer type
DFNT_NINT32	(DFNT_NATIVE DFNT_INT32)	32-bit native integer type
DFNT_NUINT32	(DFNT_NATIVE DFNT_UINT32)	32-bit native unsigned integer type
DFNT_NFLOAT32	(DFNT_NATIVE DFNT_FLOAT32)	32-bit native floating-point type
DFNT_NFLOAT64	(DFNT_NATIVE DFNT_FLOAT64)	64-bit native floating-point type

When using a FORTRAN-77 data type that is not supported, the general practice is to use another data type of the same size. For example, an 8-bit signed integer can be used to store an 8-bit unsigned integer variable unless the code relies on a sign-specific operation.

1.5.6 String and Array Specifications

In the declarations contained in the headers of FORTRAN-77 functions, the following conventions are followed:

- character*(*) x means that x refers to a string of an indefinite number of characters. It is the responsibility of the calling program to allocate enough space to hold the data to be stored in the string.
- real x(*) means that x refers to an array of reals of indefinite size and of indefinite rank. It is the responsibility of the calling program to allocate an actual array with the correct number of dimensions and dimension sizes.
- <valid numeric data type > x means that x may have one of the numeric data types listed in the Description column of Table 1A on page 6.
- <valid data type > x means that x may have any of the data types listed in the Description column of Table 1A on page 6.

1.5.7 FORTRAN-77, ANSI C and K&R C

As much as possible, we have conformed the HDF API routines to those implementations of Fortran and C that are in most common use today, namely FORTRAN-77, ANSI C and K&R C. Due to the increasing availability of ANSI C, future versions of HDF will no longer support K&R C.

As Fortran-90 is a superset of FORTRAN-77, HDF programs should compile and run correctly when using a Fortran-90 compiler.

1.6 Error Codes

The error codes defined in the HDF library are listed in the following table.

TABLE 1B HDF Error Codes

Error Code	Code Definition
DFE_NONE	No error.
DFE_FNF	File not found.
DFE_DENIED	Access to file denied.
DFE_ALROPEN	File already open.
DFE_TOOMANY	Too many AIDs or files open.
DFE_BADNAME	Bad file name on open.
DFE_BADACC	Bad file access mode.
DFE_BADOPEN	Miscellaneous open error.
DFE_NOTOPEN	File can't be closed because it hasn't been opened.
DFE_CANTCLOSE	fclose error
DFE_READERROR	Read error.
DFE_WRITEERROR	Write error.
DFE_SEEKERROR	Seek error.
DFE_RDONLY	File is read only.
DFE_BADSEEK	Attempt to seek past end of element.
DFE_PUTELEM	Hputelement error.
DFE_GETELEM	Hgetelement error.
DFE_CANTLINK	Cannot initialize link information.
DFE_CANTSYNC	Cannot synchronize memory with file.
DFE_BADGROUP	Error from DFdiread in opening a group.
DFE_GROUPSETUP	Error from DFdisetup in opening a group.
DFE_PUTGROUP	Error on putting a tag/reference number pair into a group.
DFE_GROUPWRITE	Error when writing group contents.
DFE_DFNULL	Data file reference is a null pointer.
DFE_ILLTYPE	Data file contains an illegal type: internal error.
DFE_BADDDLIST	The DD list is non-existent: internal error.
DFE_NOTDFFILE	The current file is not an HDF file and it is not zero length.
DFE_SEEDTWICE	The DD list already seeded: internal error.
DFE_NOSUCHTAG	No such tag in the file: search failed.
DFE_NOFREEDD	There are no free DD's left: internal error.
DFE_BADTAG	Illegal WILDCARD tag.
DFE_BADREF	Illegal WILDCARD reference number.
DFE_NOMATCH	No DDs (or no more DDs) that match the specified tag/reference number pair.
DFE_NOTINSET	Warning: Set contained unknown tag. Ignored.
DFE_BADOFFSET	Illegal offset specified.
DFE_CORRUPT	File is corrupted.
DFE_NOREF	No more reference numbers are available.
DFE_DUPDD	The new tag/reference number pair has been allocated.
DFE_CANTMOD	Old element doesn't exist. Cannot modify.

Error Code	Code Definition
DFE_DIFFFILES	Attempt to merge objects in different files.
DFE_BADAID	An invalid AID was received.
DFE_OPENAID	Active AIDs still exist.
DFE_CANTFLUSH	Cannot flush DD back to file.
DFE_CANTUPDATE	Cannot update the DD block.
DFE_CANTHASH	Cannot add a DD to the hash table.
DFE_CANTDELDD	Cannot delete a DD in the file.
DFE_CANTDELHASH	Cannot delete a DD from the hash table.
DFE_CANTACCESS	Cannot access specified tag/reference number pair.
DFE_CANTENDACCESS	Cannot end access to data element.
DFE_TABLEFULL	Access table is full.
DFE_NOTINTABLE	Cannot find element in table.
DFE_UNSUPPORTED	Feature not currently supported.
DFE_NOSPACE	malloc failed.
DFE_BADCALL	Routine calls were in the wrong order.
DFE_BADPTR	NULL pointer argument was specified.
DFE_BADLEN	Invalid length was specified.
DFE_NOTENOUGH	Not enough space for the data.
DFE_NOVALS	Values were not available.
DFE_ARGS	Invalid arguments passed to the routine.
DFE_INTERNAL	Serious internal error.
DFE_NORESET	Too late to modify this value.
DFE_GENAPP	Generic application level error.
DFE_UNINIT	Interface was not initialized correctly.
DFE_CANTINIT	Cannot initialize the interface the operation requires.
DFE_CANTSHUTDOWN	Cannot shut down the interface the operation requires.
DFE_BADDIM	Negative number of dimensions, or zero dimensions, was specified.
DFE_BADFP	File contained an illegal floating point number.
DFE_BADDATATYPE	Unknown or unavailable data type was specified.
DFE_BADMCTYPE	Unknown or unavailable machine type was specified.
DFE_BADNUMTYPE	Unknown or unavailable number type was specified.
DFE_BADORDER	Unknown or illegal array order was specified.
DFE_RANGE	Improper range for attempted access.
DFE_BADCONV	Invalid data type conversion was specified.
DFE_BADTYPE	Incompatible types were specified.
DFE_BADSCHEME	Unknown compression scheme was specified.
DFE_BADMODEL	Invalid compression model was specified.
DFE_BADCODER	Invalid compression encoder was specified.
DFE_MODEL	Error in the modeling layer of the compression operation.
DFE_CODER	Error in the encoding layer of the compression operation.
DFE_CINIT	Error in encoding initialization.
DFE_CDECODE	Error in decoding compressed data.
DFE_CENCODE	Error in encoding compressed data.
DFE_CTERM	Error in encoding termination.
DFE_CSEEK	Error seeking in an encoded dataset.
DFE_MINIT	Error in modeling initialization.
DFE_COMPINFO	Invalid compression header.

Error Code	Code Definition
DFE_CANTCOMP	Cannot compress an object.
DFE_CANTDECOMP	Cannot decompress an object.
DFE_NODIM	A dimension record was not associated with the image.
DFE_BADRIG	Error processing a RIG.
DFE_RINOTFOUND	Cannot find raster image.
DFE_BADATTR	Invalid attribute.
DFE_BADTABLE	The nsdg table has incorrect information.
DFE_BADSDG	Error in processing an SDG.
DFE_BADNDG	Error in processing an NDG.
DFE_VGSIZE	Too many elements in the vgroup.
DFE_VTAB	Element not in vtab[].
DFE_CANTADDELEM	Cannot add the tag/reference number pair to the vgroup.
DFE_BADVGNAME	Cannot set the vgroup name.
DFE_BADVGCLASS	Cannot set the vgroup class.
DFE_BADFIELDS	Invalid fields string passed to vset routine.
DFE_NOVS	Cannot find the vset in the file.
DFE_SYMSIZE	Too many symbols in the users table.
DFE_BADATTACH	Cannot write to a previously attached vdata.
DFE_BADVSNAME	Cannot set the vdata name.
DFE_BADVSCLASS	Cannot set the vdata class.
DFE_VSWRITE	Error writing to the vdata.
DFE_VSREAD	Error reading from the vdata.
DFE_BADVH	Error in the vdata header.
DFE_VSCANTCREATE	Cannot create the vdata.
DFE_VGCANTCREATE	Cannot create the vgroup.
DFE_CANTATTACH	Cannot attach to a vdata or vset.
DFE_CANTDETACH	Cannot detach a vdata or vset with write access.
DFE_BITREAD	A bit read error occurred.
DFE_BITWRITE	A bit write error occurred.
DFE_BITSEEK	A bit seek error occurred.
DFE_TBBTINS	Failed to insert the element into tree.
DFE_BVNEW	Failed to create a bit vector.
DFE_BVSET	Failed when setting a bit in a bit vector.
DFE_BVGET	Failed when getting a bit in a bit vector.
DFE_BVFIND	Failed when finding a bit in a bit vector.

Section 2

HDF Routine Reference

2.1 Reference Section Overview

This section of the Reference Manual contains a listing of every routine contained in the HDF version 4.1r4 library. For each interface, the pages are organized alphabetically according to the C routine name. Each page addresses one C routine and the related FORTRAN-77 routines, and takes the following form:

Routine_Name

return_type function_name(type1 parameter1, type2 parameter2, ..., typeN parameterN)

parameter 1 IN/OUT: Definition of the first parameter

parameter2 IN/OUT: Definition of the second parameter

parameterN IN/OUT Definition of the Nth parameter

Purpose Section containing the functionality of the routine.

Return value Section describing the return value, if any.

Description This optional section describes the proper use of the routine, the specification

of the parameters, and any special circumstances surrounding the use of the routine. This section also identifies any prerequisite routines and provides

appropriate references.

FORTRAN This section provides a synopsis of the equivalent FORTRAN-77

routine or routines.

ANannlen/afannlen

int32 ANannlen(int32 ann_id)

ann_id IN: Annotation identifier returned by ANcreate, ANcreatef, or

ANselect

Purpose Returns the length of an annotation.

Return value Returns the length of the annotation or FAIL (or -1) otherwise.

Description ANannlen returns the number of characters contained in the annotation

specified by the parameter ann_id. This function is commonly used to

determine the size of a buffer to store the annotation upon reading.

FORTRAN integer function afannlen(ann_id)

integer ann_id

ANannlist/afannlist

intn ANannlist(int32 an_id, ann_type annot_type, uint16 obj_tag, uint16 obj_ref, int32 *ann_list)

an_id IN: AN interface identifier returned by **ANstart**

annot_type IN: Type of the annotation

obj_tag IN: Tag of the object

obj_ref IN: Reference number of the object

ann_list OUT: Buffer for the annotation identifiers

Purpose Retrieves the annotation identifiers of an object.

Return value Returns SUCCEED (or 0) or FAIL (or -1) otherwise.

Description ANannlist obtains a list of identifiers of the annotations that are of the type

specified by the parameter *annot_type* and are attached to the object identified by its tag, *obj_tag*, and its reference number, *obj_ref*.

Since this routine is implemented only to obtain the identifiers of data annotations and not file annotations, the valid values of *annot_type* are AN_DATA_LABEL (or 0) and AN_DATA_DESC (or 1). To obtain file annotation identifiers, use **ANfileinfo** to determine the number of file labels and descriptions, and then use **ANselect** to obtain each file annotation identifier.

Sufficient space must be allocated for *ann_list* to hold the list of annotation identifiers. This can be done by using **ANnumann** to obtain the number of annotation identifiers to be retrieved, and then allocating memory for *ann_list* using this number.

```
FORTRAN
```

```
integer function afannlist(an_id, annot_type, obj_tag, obj_ref,
ann_list)
```

```
integer ann list(*)
```

integer an_id, obj_tag, obj_ref, annot_type

ANatype2tag/afatypetag

uint16 ANatype2tag(ann_type *annot_type)

annot_type IN: Type of the annotation

Purpose Returns the annotation tag corresponding to an annotation type.

Return value Returns the annotation tag (ann_tag) if successful, and DFTAG_NULL (or 0)

otherwise.

Description ANatype2tag returns the tag that corresponds to the annotation type specified

by the parameter *annot_type*.

The following table lists the valid values of *annot_type* in the left column and the corresponding values for the returned annotation tag on the right.

Annotation Type	Annotation Tag
AN_DATA_LABEL (or 0)	DFTAG_DIL (or 104)
AN_DATA_DESC (or 1)	DFTAG_DIA (or 105)
AN_FILE_LABEL (or 2)	DFTAG_FID (or 100)
AN_FILE_DESC (or 3)	DFTAG_FD (or 101)

FORTRAN integer function afatypetag(annot_type)

integer annot_type

ANcreate/afcreate

int32 ANcreate(int32 an_id, uint16 obj_tag, uint16 obj_ref, ann_type annot_type)

an_id IN: AN interface identifier returned by **ANstart**

obj_tag IN: Tag of the object to be annotated

obj_ref IN: Reference number of the object to be annotated

annot_type IN: Type of the data annotation

Purpose Creates a data annotation for an object.

Return value Returns the data annotation identifier (ann_id) if successful and FAIL (or -1)

otherwise.

Description ANcreate creates a data annotation of type *annot_type* for the object specified

by its tag, *obj_tag*, and its reference number, *obj_ref*. The returned data annotation identifier can represent either a data label or a data description.

Valid values for *annot_type* are An_data_label (or 0) or An_data_desc (or 1).

Use **ANcreatef** to create a file annotation.

Currently, the user must write to a newly-created annotation before creating another annotation of the same type. Creating two consecutive annotations of

the same type causes the second call to ${\bf ANcreate}$ to return <code>FAIL</code> (or -1).

FORTRAN integer function afcreate(an_id, obj_tag, obj_ref, annot_type)

integer an_id, obj_tag, obj_ref, annot_type

ANcreatef/affcreate

int32 ANcreatef(int32 an_id, ann_type annot_type)

an_id IN: AN interface identifier returned by **ANstart**

annot_type IN: Type of the file annotation

Purpose Creates a file annotation.

Return value Returns the file annotation identifier (ann_id) if successful and FAIL (or -1)

otherwise.

Description ANcreatef creates a file annotation of the type specified by the parameter

annot_type. The file annotation identifier returned can either represent a file

label or a file description.

Valid values for *annot_type* are AN_FILE_LABEL (or 2) and AN_FILE_DESC (or 3).

Use ANcreate to create a data annotation.

Currently, the user must write to a newly-created annotation before creating another annotation of the same type. Creating two consecutive annotations of the same type causes the second call to **ANcreate** to return FAIL (or -1).

FORTRAN integer function affcreate(an_id, annot_type)

integer an_id, annot_type

ANend/afend

int32 ANend(int32 an_id)

an_id IN: AN interface identifier returned by ANstart

Purpose Terminates access to an AN interface.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description ANend terminates access to the AN interface identified by an_id, which is

previously initialized by a call to ANstart. Note that there must be one call to

ANend for each call to **ANstart**.

FORTRAN integer function afend(an_id)

integer an_id

ANendaccess/afendaccess

intn ANendaccess(int32 ann_id)

ann_id IN: Annotation identifier returned by ANcreate, ANcreatef or ANselect

Purpose Terminates access to an annotation.

Return value Returns Successful and FAIL (or -1) otherwise.

Description ANendaccess terminates access to the annotation identified by the parameter

ann_id. Note that there must be one call to ANendaccess for every call to

ANselect, ANcreate or ANcreatef.

FORTRAN integer function afendaccess(ann_id)

integer ann_id

ANfileinfo/affileinfo

intn ANfileinfo(int32 an_id, int32 *n_file_labels, int32 *n_file_descs, int32 *n_data_labels, int32 *n_data_descs)

an_id IN: AN interface identifier returned by **ANstart**

n_file_labels OUT: Number of file labels

n_file_descs OUT: Number of file descriptions

n_data_labels OUT: Number of data labels

n_data_descs OUT: Number of data descriptions

Purpose Retrieves the number of annotations of each type in a file.

Return value Returns Succeed (or 0) if successful or Fail (or -1) otherwise.

Description ANfileinfo retrieves the total

ANfileinfo retrieves the total number of the four kinds of annotations and stores them in the appropriate parameters. The total number of data labels of all data objects in the file is stored in n_data_labels . The total number of data descriptions of all data objects in the file is stored in n_data_descs . The total number of file labels is stored in n_file_labels and the total number of file descriptions in n_file_descs .

Note that the numbers of data labels and descriptions refer to the total number of data labels and data descriptions in the file, not for a specific object. Use **ANnumann** to determine these numbers for a specific object.

This routine is generally used to find the range of acceptable indices for **ANselect** calls.

FORTRAN integ

```
integer function affileinfo(an_id, n_file_labels, n_file_descs,
n_data_labels, n_data_descs)
```

```
integer an_id, n_file_labels, n_file_descs
```

integer n_data_labels, n_data_descs

ANget_tagref/afgettagref

int32 ANget_tagref(int32 an_id, int32 index, ann_type annot_type, uint16 *ann_tag, uint16 *ann_ref)

an_id IN: AN interface identifier returned by **ANstart**

index IN: Index of the annotation

annot_type IN: Type of the annotation

ann_tag OUT: Tag of the annotation

ann_ref OUT: Reference number of the annotation

Purpose Retrieves the tag/reference number pair of an annotation given its index and

type.

Return value Returns Succeed (or 0) if successful or Fail (or -1) otherwise.

DescriptionANget_tagref retrieves the tag and reference number of the annotation identified by its index, the parameter *index*, and by its annotation type, the parameter *annot_type*. The tag is stored in the parameter *ann_tag* and the

reference number is stored in the parameter ann_ref.

The parameter *index* is a nonnegative integer and is less than the total number of annotations of type *annot_type* in the file. Use **ANfileinfo** to obtain the total number of annotations of each type in the file.

The following table lists the valid values of the parameter *annot_type* in the left column, and the corresponding values of the parameter *ann_tag* in the right column.

Annotation Type	Annotation Tag
AN_DATA_LABEL (or 0)	DFTAG_DIL (or 104)
AN_DATA_DESC (or 1)	DFTAG_DIA (or 105)
AN_FILE_LABEL (or 2)	DFTAG_FID (or 100)
AN_FILE_DESC (or 3)	DFTAG_FD (or 101)

FORTRAN

integer function afgettagref(an_id, index, annot_type, ann_tag, ann_ref)

integer an_id, index, annot_type

integer ann tag, ann ref

ANid2tagref/afidtagref

int32 ANid2tagref(int32 ann_id, uint16 *ann_tag, uint16 *ann_ref)

ann_id IN: Annotation identifier returned by ANselect, ANcreate or ANcreatef

ann_tag OUT: Tag of the annotation

ann_ref OUT: Reference number of the annotation

Purpose Retrieves the tag/reference number pair of an annotation given its identifier.

Return value Returns Succeed (or 0) if successful or Fail (or -1) otherwise.

Description ANid2tagref retrieves the tag/reference number pair of the annotation

identified by the parameter ann_id. The tag is stored in the parameter ann_tag

and the reference number is stored in the parameter ann_ref.

Possible values returned in *ann_tag* are DFTAG_DIL (or 104) for a data label, DFTAG DIA (or 105) for a data description, DFTAG FID (or 100) for a file label

and DFTAG FD (or 101) for a file description.

FORTRAN integer function afidtagref(ann_id, ann_tag, ann_ref)

integer ann_id, ann_tag, ann_ref

ANnumann/afnumann

intn ANnumann(int32 an_id, ann_type annot_type, uint16 obj_tag, uint16 obj_ref)

an_id IN: AN interface identifier returned by **ANstart**

annot_type IN: Type of the annotation

obj_tag IN: Tag of the object

obj_ref IN: Reference number of the object

Purpose Returns the number of annotations of a given type attached to an object.

Return value Returns the number of annotations or FAIL (or -1) otherwise.

Description ANnumann returns the total number of annotations that are of type *annot_type*

and that are attached to the object identified by its tag, obj_tag, and its

reference number, obj_ref.

Since this routine is implemented only to obtain the total number of data annotations and not file annotations, the valid values of *annot_type* are AN DATA LABEL (or 0) and AN DATA DESC (or 1). To obtain the total number of

file annotations or all data annotations, use ANfileinfo.

FORTRAN integer function afnumann(an_id, annot_type, obj_tag, obj_ref)

integer an_id, obj_tag, obj_ref, annot_type

ANreadann/afreadann

int32 ANreadann(int32 ann_id, char* ann_buf, int32 ann_length)

ann_id IN: Annotation identifier returned by ANcreate, ANcreate or ANselect

ann_buf OUT: Buffer for the annotation

ann_length IN: Length of the buffer ann_buf

Purpose Reads an annotation.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description ANreadann reads the annotation identified by the parameter *ann_id* and stores

the annotation in the parameter *ann_buf*.

The parameter ann_length specifies the size of the buffer ann_buf . If the length of the file or data label to be read is greater than or equal to ann_length , the label will be truncated to $ann_length - 1$ characters. If the length of the file or data description is greater than ann_length , the description will be truncated to ann_length characters. The HDF library adds a <code>NULL</code> character to the retrieved label but not to the retrieved description. The user must add a <code>NULL</code> character to the retrieved description if the C library string functions are to operate on this

description.

FORTRAN integer function afreadann(ann_id, ann_buf, ann_length)

integer ann_id, ann_length

character*(*) ann_buf

ANselect/afselect

int32 ANselect(int32 an_id, int32 index, ann_type annot_type)

an_id IN: AN interface identifier returned by **ANstart**

index IN: Location of the annotation in the file

annot_type IN: Type of the annotation

Purpose Obtains an existing annotation.

Return value Returns the annotation identifier (ann_id) if successful or FAIL (or -1)

otherwise.

Description ANselect obtains the identifier of the annotation specified by its index, *index*,

and by its annotation type, annot_type.

The parameter *index* is a nonnegative integer and is less than the total number of annotations of type *annot_type* in the file. Use **ANfileinfo** to obtain the total

number of annotations of each type in the file.

Valid values of annot_type are an_data_label (or 0), an_data_desc (or 1),

AN_FILE_LABEL (or 2), and AN_FILE_DESC (or 3).

FORTRAN integer function afselect(an_id, index, annot_type)

integer an_id, index

integer annot_type

ANstart/afstart

int32 ANstart(int32 file_id)

file_id IN: File identifier returned by **Hopen**

Purpose Initializes the AN interface.

Return value Returns the AN interface identifier (an_id) if successful and FAIL (or -1)

otherwise.

Description ANstart initializes the AN interface for the file identified by the parameter

file_id. A call to **ANstart** is required before any AN functions can be invoked. **ANstart** is used with the **ANend** function to define the extent of AN interface

session. A call to **ANend** is required for each call to **ANstart**.

FORTRAN integer function afstart(file_id)

integer file_id

ANtag2atype/aftagatype

ann_type ANtag2atype(uint16 ann_tag)

ann_tag IN: Tag of the annotation

Purpose Returns the annotation type corresponding to an annotation tag.

Return value Returns the annotation type if successful or AN UNDEF (or -1) otherwise.

Description ANtag2atype returns the annotation type that corresponds to the annotation tag

specified by the parameter *ann_tag*.

The following table lists the valid values of *ann_tag* in the left column and the corresponding values of the returned annotation type in the right column.

Annotation Tag	Annotation Type
DFTAG_DIL (or 104)	AN_DATA_LABEL (or 0)
DFTAG_DIA (or 105)	AN_DATA_DESC (or 1)
DFTAG_FID (or 100)	AN_FILE_LABEL (or 2)
DFTAG_FD (or 101)	AN_FILE_DESC (or 3)

FORTRAN integer function aftagatype(ann_tag)

integer ann_tag

ANtagref2id/aftagrefid

int32 ANtagref2id(int32 an_id, uint16 ann_tag, uint16 ann_ref)

an_id IN: AN interface identifier returned by **ANstart**

ann_tag IN: Tag of the annotation

ann_ref IN: Reference number of the annotation

Purpose Returns the identifier of an annotation given its tag/reference number pair.

Return value Returns the annotation identifier (ann_id) if successful and FAIL (or -1)

otherwise.

Description ANtagref2id returns the identifier of the annotation specified by its tag,

ann_tag, and its reference number, ann_ref.

Valid values of *ann_tag* are DFTAG_DIL (or 104) for a data label, DFTAG_DIA (or 105) for a data description, DFTAG_FID (or 100) for a file label, and DFTAG_FD

(or 101) for a file description.

FORTRAN integer function aftagrefid(an_id, ann_tag, ann_ref)

integer an_id, ann_tag, ann_ref

ANwriteann/afwriteann

int32 ANwriteann(int32 ann_id, char* ann, int32 ann_length)

ann_id IN: Annotation identifier returned by ANcreate, ANcreatef, or ANselect

ann IN: Text to be written to the annotation

ann_length IN: Length of the annotation text

Purpose Writes an annotation.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description ANwriteann writes the annotation text provided in the parameter ann to the

annotation specified by the parameter ann_id. The parameter ann_length

specifies the number of characters in the annotation text.

If the annotation has already been written with text, ANwriteann will

overwrite the current text.

FORTRAN integer function afwriteann(ann_id, ann, ann_length)

integer ann_id, ann_length

character*(*) ann

GRattrinfo/mgatinf

intn GRattrinfo(int32 [obj]_id, int32 attr_index, char *name, int32 *data_type, int32 *count)

[obj]_id IN: Raster image identifier (ri_id), returned by GRcreate or GRselect,

or GR interface identifier (gr_id), returned by GRstart

attr_index IN: Index of the attribute

name OUT: Buffer for the name of the attribute

data_type OUT: Data type of the attribute count OUT: Number of attribute values

Purpose Retrieves information about an attribute.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description

GRattrinfo retrieves the name, data type, and number of values of the attribute, specified by its index, *attr_index*, for the data object identified by the parameter *obj_id*. The name is stored in the parameter *name*, the data type is stored in the parameter *data_type*, and the number of values is stored in the parameter *count*. If the value of any of the output parameters is NULL, the corresponding information will not be retrieved.

The value of the parameter *attr_index* can be obtained using **GRfindattr**, **GRnametoindex** or **GRreftoindex**, depending on available information. Valid values of *attr_index* range from 0 to the total number of attributes attached to the object - 1. The total number of attributes attached to the file can be obtained using the routine **GRfileinfo**. The total number of attributes attached to an image can be obtained using the routine **GRgetiminfo**.

```
FORTRAN
```

```
integer [obj]_id, data_type, attr_index, count
```

character*(*) name

GRcreate/mgcreat

int32 GRcreate(int32 *gr_id*, char *name, int32 *ncomp*, int32 *data_type*, int32 *interlace_mode*, int32 *dim_sizes*[2])

gr_id IN: GR interface identifier returned by **GRstart**

name IN: Name of the raster image

ncomp IN: Number of pixel components in the image

data_type IN: Type of the image data

interlace_mode IN: Interlace mode of the image data

dim_sizes IN: Size of each dimension of the image

Purpose Creates a new raster image.

Return value Returns a raster image identifier if successful and FAIL (or -1) otherwise.

Description GRcreate creates a raster image with the values provided in the parameters name, ncomp, data_type, interlace_mode and dim_sizes.

The parameter *name* specifies the name of the image and must not be NULL. The length of the name should not be longer than MAX GR NAME (or 256).

The parameter *ncomp* specifies the number of pixel components in the raster image and must have a value of at least 1.

The parameter *data_type* specifies the type of the raster image data and can be any of the data types supported by the HDF library. The data types supported by HDF are listed in Table 1A in Section I of this manual.

The parameter *interlace_mode* specifies the interlacing in which the raster image is to be written. The valid values of *interlace_mode* are: MFGR_INTERLACE_PIXEL (or 0), MFGR_INTERLACE_LINE (or 1) and MFGR_INTERLACE_COMPONENT (or 2).

The array *dimsizes* specifies the size of the two dimensions of the image. The dimensions must be specified and their values must be greater than 0.

Once a raster image has been created, it is not possible to change its name, data type, dimension sizes or number of pixel components. However, it is possible to create a raster image and close the file before writing any data values to it. Later, the values can be added to or modified in the raster image, which then can be obtained using **GRselect**.

Images created with the GR interface are actually written to disk in pixel interlace mode; any user-specified interlace mode is stored in the file with the image and the image is automatically converted to that mode when it is read with a GR interface function.

Note

Regarding an important difference between the SD and GR interfaces:

The SD and GR interfaces differ in the correspondence between the dimension order in parameter arrays such as *start*, *stride*, *edge*, and *dimsizes* and the dimension order in the *data* array. See the **SDreaddata** and **GRreadimage** reference manual pages for discussions of the SD and GR approaches, respectively.

When writing applications or tools to manipulate both images and twodimensional SDs, this crucial difference between the interfaces must be taken into account. While the underlying data is stored in row-major order in both cases, the API parameters are not expressed in the same way. Consider the example of an SD data set and GR image that are stored as identically-shaped arrays of X columns by Y rows and accessed via the **SDreaddata** and **GRreadimage** functions, respectively. Both functions take the parameters start, stride, and edge.

- For **SDreaddata**, those parameters are expressed in (y,x) or [row,column] order. For example, start[0] is the starting point in the Y dimension and start[1] is the starting point in the X dimension. The same ordering holds true for all SD data set manipulation functions.
- For **GRreadimage**, those parameters are expressed in (x,y) or [column,row] order. For example, start[0] is the starting point in the X dimension and start[1] is the starting point in the Y dimension. The same ordering holds true for all GR functions manipulating image data.

FORTRAN

```
integer gr_id, data_type, interlace_mode, ncomp, dim_sizes(2)
character*(*) name
```

GRend/mgend

intn GRend(int32 gr_id)

 gr_id IN: GR interface identifier returned by **GRstart**

Purpose Terminates the GR interface session.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description GRend terminates the GR interface session identified by the parameter $gr_{\perp}id$.

GRend, together with **GRstart**, defines the extent of a GR interface session. **GRend** disposes of the internal structures initialized by the corresponding call to **GRstart**. There must be a call to **GRend** for each call to **GRstart**; failing to

provide one may cause loss of data.

GRstart and **GRend** do not manage file access; use **Hopen** and **Hclose** to open and close HDF files. **Hopen** must be called before **GRstart** and **Hclose**

must be called after **GRend**.

FORTRAN integer function mgend(gr_id)

integer gr_id

GRendaccess/mgendac

intn GRendaccess(int32 ri_id)

ri_id IN: Raster image identifier returned by **GRcreate** or **GRselect**

Purpose Terminates access to a raster image.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description GRendaccess terminates access to the raster image identified by the parameter

ri_id and disposes of the raster image identifier. This access is initiated by either **GRselect** or **GRcreate**. There must be a call to **GRendaccess** for each call to **GRselect** or **GRcreate**; failing to provide this will result in loss of data. Attempts to access a raster image identifier disposed of by **GRendaccess** will

result in an error condition.

FORTRAN integer function mgendac(ri_id)

integer ri_id

GRfileinfo/mgfinfo

intn GRfileinfo(int32 gr_id, int32 *n_images, int32 *n_file_attrs)

gr_id IN: GR interface identifier returned by **GRstart**

n_images OUT: Number of raster images in the file

n_file_attrs OUT: Number of global attributes in the file

Purpose Retrieves the number of raster images and the number of global attributes in

the file.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description GRfileinfo retrieves the number of raster images and the number of global attributes for the GR interface identified by the parameter gr_id , and stores

them into the parameters n_images and n_file_attrs , respectively.

The term "global attributes" refers to attributes that are assigned to the file instead of individual raster images. These attributes are created by **GRsetattr** with the object identifier parameter set to a GR interface identifier (*gr_id*)

rather than a raster image identifier (*ri_id*).

GRfileinfo is useful in finding the range of acceptable indices for GRselect

calls.

FORTRAN integer function mgfinfo(gr_id, n_images, n_file_attrs)

integer gr_id, n_images, n_file_attrs

GRfindattr/mgfndat

int32 GRfindattr(int32 [obj]_id, char *attr_name)

[obj]_id IN: Raster image identifier (ri_id), returned by **GRcreate** or **GRselect**,

or GR interface identifier (gr_id) , returned by **GRstart**

attr_name IN: Name of the attribute

Purpose Finds the index of a data object's attribute given an attribute name.

Return value Returns the index of the attribute if successful and FAIL (or -1) otherwise.

Description GRfindattr returns the index of the attribute whose name is specified by the

parameter *attr_name* for the object identified by the parameter *obj_id*.

FORTRAN integer function mgfndat([obj]_id, attr_name)

integer [obj]_id

character*(*) attr_name

GRgetattr/mggnatt/mggcatt

intn GRgetattr(int32 [obj]_id, int32 attr_index, VOIDP values)

[obj] id IN: Raster image identifier (ri id), returned by GRcreate or GRselect,

or GR interface identifier (*gr_id*), returned by **GRstart**

attr_index IN: Index of the attribute

values OUT: Buffer for the attribute values

Purpose Reads the values of an attribute for a data object.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description GRgetattr obtains all values of the attribute that is specified by its index, attr_index, and is attached to the object identified by the parameter obj_id.

The values are stored in the buffer values.

The value of the parameter *attr_index* can be obtained by using **GRfindattr**, **GRnametoindex**, or **GRreftoindex**, depending on available information. Valid values of *attr_index* range from 0 to the total number of attributes of the object - 1. The total number of attributes attached to the file can be obtained using the routine **GRfileinfo**. The total number of attributes attached to the image can be obtained using the routine **GRgetiminfo**.

GRgetattr only reads all values assigned to the attribute and not a subset.

Note that there are two FORTRAN-77 versions of this routine; one for numeric data (**mggnatt**) and the other for character data (**mggcatt**).

```
FORTRAN integer function mggnatt([obj]_id, attr_index, values)
```

```
integer [obj]_id, attr_index
```

<valid numeric data type> values(*)

integer function mggcatt([obj]_id, attr_index, values)

integer [obj]_id, attr_index

character*(*) values

GRgetchunkinfo/mggichnk

intn GRgetchunkinfo(int32 ri_id, HDF_CHUNK_DEF *cdef, int32 *flag)

ri_id IN: Raster image identifier returned by **GRcreate** or **GRselect**

C only:

cdef OUT: Pointer to the chunk definition

flag OUT: Pointer to the compression flag

Fortran only:

dim_length OUT: Array of chunk dimensions

flag OUT: Compression flag

Purpose Retrieves chunking information for a raster image.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description

GRgetchunkinfo retrieves chunking information about the raster image identified by the parameter ri_id into the parameters cdef and flags in C, and into the parameters dim_length and flag in Fortran. Note that only chunk dimensions are retrieved, compression information is not available.

The value returned in the parameter *flag* indicates if the raster image is not chunked, chunked, or chunked and compressed. The following table shows the possible values of the parameter *flag* and the corresponding characteristics of the raster image.

Values of flag in C	Values of <i>flag</i> in Fortran	Raster Image Characteristics
HDF_NONE	-1	Not chunked
HDF_CHUNK	0	Chunked and not compressed
HDF_CHUNK HDF_COMP	1	Chunked and compressed with either the run-length encoding (RLE), Skipping Huffman or GZIP compres- sion algorithms

In C, if the raster image is chunked and not compressed, **GRgetchunkinfo** fills the array chunk_lengths in the union cdef with the values of the corresponding chunk dimensions. If the raster image is chunked and compressed, **GRgetchunkinfo** fills the array chunk_lengths in the structure comp of the union cdef with the values of the corresponding chunk dimensions. Refer to the page on **GRsetchunk** in this manual for specific information on the union hdf_chunk_def. In Fortran, chunk dimensions are retrieved into the array dim_length. If the chunk length for each dimension is not needed, NULL can be passed in as the value of the parameter cdef in C.

FORTRAN integer function mggichnk(ri_id, dim_length, flag)

integer ri_id, dim_length, flag

GRgetcompress/mggcompress

intn GRgetcompress(int32 ri_id, comp_coder_t *comp_type, comp_info *c_info)

ri_id IN: Raster image identifier returned by **GRcreate** or **GRselect**

comp_type OUT: Type of compression

C only:

 c_{info} OUT: Pointer to compression information structure

Fortran only:

comp_prm OUT: Compression parameters array

Purpose Retrieves raster image data compression type and compression information.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description GRgetcompress retrieves the compression type and compression information for the specified raster image.

The compression method is returned in the parameter *comp_type*. Valid values of *comp_type* are as follows:

```
COMP_CODE_NONE (or 0) for no compression

COMP_CODE_RLE (or 1) for RLE run-length encoding

COMP_CODE_SKPHUFF (or 3) for Skipping Huffman compression

COMP_CODE_DEFLATE (or 4) for GZIP compression

COMP_CODE_SZIP (or 5) for Szip compression

COMP_CODE_JPEG (or 7) for JPEG compression
```

When a compression method requires additional parameters, those values are returned in the *c_info* struct in C and the array parameter *comp_prm* in Fortran.

The c_i for struct is of type comp_info, contains algorithm-specific information for the library compression routines, and is described in the hoomp.h header file and in the **GRsetcompress** entry in this reference manual.

The *comp_prm* parameter is an array of one element:

- With Skipping Huffman compression, comp_prm(1) contains the skip value, skphuff_skp_size.
- In the case of GZIP compression, *comp_prm(1)* contains the deflation value, *deflate_value*.
- comp_prm is ignored with other compression methods. (There are no relevant RLE parameters and the quality and force_baseline data are not available for JPEG images. If GRgetcompress is called for either an RLE or a JPEG image, the function will return only the compression type; c_info will contain only zeros.)

```
FORTRAN integer function mggcompress(ri_id, comp_type, comp_prm)

integer ri_id, comp_type, comp_prm(1)
```

GRgetiminfo/mggiinf

intn GRgetiminfo(int32 ri_id, char *gr_name, int32 *ncomp, int32 *data_type, int32 *interlace_mode, int32 dim_sizes[2], int32 *num_attrs)

ri_id	IN:	Raster image identifier returned by GRcreate or GRselect
gr_name	OUT:	Buffer for the name of the raster image
ncomp	OUT:	Number of components in the raster image
data_type	OUT:	Data type of the raster image data
interlace_mode	OUT:	Interlace mode of the stored raster image data
dim_sizes	OUT:	Sizes of raster image dimension
num_attrs	OUT:	Number of attributes attached to the raster image

Purpose Retrieves general information about a raster image.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description

GRgetiminfo retrieves the name, number of components, data type, interlace mode, dimension sizes, and number of attributes of the raster image identified by the parameter ri_id .

GRgetiminfo stores the name, number of components, data type, interlace mode and dimension sizes of the image in the parameters gr_name , ncomp, $data_type$, $interlace_mode$, and dim_sizes , respectively. It also retrieves the number of attributes attached to the image into the parameter num_attrs . If the value of any of the output parameters are set to <code>NULL</code> in C, the corresponding information will not be retrieved.

The buffer gr_name is assumed to have sufficient space allocated to store the entire name of the raster image.

The valid values of the parameter *data_type* are listed in Table 1A in Section I of this manual.

FORTRAN

```
integer ri_id, ncomp, data_type, interlace_mode, num_attrs
```

integer dim_sizes[2]
character*(*) gr_name

GRgetlutid/mggltid

int32 GRgetlutid(int32 ri_id, int32 pal_index)

ri_id IN: Raster image identifier returned by **GRcreate** or **GRselect**

pal_index IN: Index of the palette

Purpose Gets the identifier of a palette given its index.

Return value Returns the palette identifier if successful and FAIL (or -1) otherwise.

Description GRgetlutid gets the identifier of the palette attached to the raster image

identified by the parameter ri_id. The palette is identified by its index,

pal_index.

Currently, only one palette can be assigned to a raster image, which means that

pal_index should always be set to 0.

FORTRAN integer function mggltid(ri_id, pal_index)

integer ri_id, pal_index

GRgetlutinfo/mgglinf

intn GRgetlutinfo(int32 pal_id, int32 *ncomp, int32 *data_type, int32 *interlace_mode, int32 *num_entries)

pal_id IN: Palette identifier returned by **GRgetlutid**

ncomp OUT: Number of components in the palette

data_type OUT: Data type of the palette

interlace_mode OUT: Interlace mode of the stored palette data

num_entries OUT: Number of color lookup table entries in the palette

Purpose Retrieves information about a palette.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description GRgetlutinfo retrieves the number of pixel components, data type, interlace

mode, and number of color lookup table entries of the palette identified by the parameter *pal_id*. These values are stored in the parameters *ncomp*, *data_type*, *interlace_mode*, and *num_entries*, respectively. In C if the value of any of the output parameters are set to NULL, the corresponding information will not be

retrieved.

FORTRAN integer function mgglinf(pal_id, ncomp, data_type, interlace_mode,

num_entries)

integer pal_id, ncomp, data_type, interlace_mode, num_entries

GRgetnluts/mggnluts

intn GRgetnluts(int32 ri_id)

ri_id IN: Data set identifier returned by **GRcreate** or **GRselect**

Purpose Retrieves the number of palettes for an image.

Return value Returns number of palettes (1 or 0) if successful and FAIL (or -1) otherwise.

Description GRgetnluts retrieves the number of palettes (or color look-up tables,

commonly abbreviated as LUTs) available for the specified raster image.

There can currently be either 0 or 1 palettes assigned to an image. If multiple palettes are supported in a future release, this function may return values

greater than 1.

FORTRAN integer function mggnluts(ri_id)

integer ri_id

GRidtoref/mgid2rf

uint16 GRidtoref(int32 ri_id)

ri_id IN: Raster image identifier returned by **GRselect** or **GRcreate**

Purpose Maps a raster image identifier to a reference number.

Return value Returns the reference number of the raster image if successful and 0 otherwise.

Description GRidtoref returns the reference number of the raster image identified by the

parameter ri_id.

This routine is commonly used for the purpose of annotating the raster image

or including the raster image within a vgroup.

FORTRAN integer function mgid2rf(ri_id)

integer ri_id

GRluttoref/mglt2rf

uint16 GRluttoref(int32 pal_id)

pal_id IN: Palette identifier returned by **GRgetlutid**

Purpose Maps a palette identifier to a reference number.

Return value Returns the reference number of the palette if successful or 0 otherwise.

Description GRluttoref returns the reference number of the palette identified by the

parameter *pal_id*.

This routine is commonly used for the purpose of annotating the palette or

including the palette within a vgroup.

FORTRAN integer function mglt2rf(pal_id)

integer pal_id

GRnametoindex/mgn2ndx

int32 GRnametoindex(int32 *gr_id*, char *gr_*name*)

gr_id IN: GR interface identifier returned by **GRstart**

ri_name IN: Name of the raster image

Purpose Maps the name of a raster image to an index.

Return value Returns the index of the raster image if successful and FAIL (or -1) otherwise.

Description GRnametoindex returns, for the GR interface identified by the parameter

 gr_id , the index (*index*) of the raster image named gr_name .

The value of index can be passed into GRselect to obtain the raster image

identifier (ri_id).

FORTRAN integer function mgn2ndx(gr_id, gr_name)

integer gr_id

character*(*) gr_name

GRreadchunk/mgrchnk/mgrcchnk

intn GRreadchunk(int32 ri_id, int32 *origin, VOIDP datap)

ri_id IN: Raster image identifier returned by **GRcreate** or **GRselect**

origin IN: Origin of the chunk to be readdatap IN: Buffer for the chunk to be read

Purpose Reads a data chunk from a chunked raster image (pixel-interlace only)

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description GRreadchunk reads the entire chunk of data from the chunked raster image

identified by the parameter ri_id and stores it in the buffer datap. Chunk to be read is specified by the parameter origin. This function has less overhead than **GRreadimage** and should be used whenever an entire chunk of data is to be

read.

GRreadchunk will return FAIL (or -1) when an attempt is made to use it to

read from a non-chunked raster image.

The parameter *origin* is a two-dimensional array which specifies the coordinates of the chunk according to the chunk position in the overall chunk array. Refer to Chapter 8, "General Raster Images (GR API)," in the *HDF*

User's Guide.

The buffer *datap* contains the chunk data organized in pixel interlace mode.

```
FORTRAN integer mgrchnk(ri_id, origin, datap)
```

```
integer ri_id, origin(2)
```

<valid_numeric_datatype> datap(*)

integer mgrcchnk(ri id, origin, char datap)

integer ri_id, origin(2)

character*(*) char_datap

GRreadimage/mgrdimg/mgrcimg

intn GRreadimage(int32 ri_id, int32 start[2], int32 stride[2], int32 edge[2], VOIDP data)

ri_id IN: Raster image identifier returned by **GRcreate** or **GRselect**

start IN: Array specifying the starting location from where raster image data

is read

stride IN: Array specifying the interval between the values that will be read

along each dimension

edge IN: Array specifying the number of values to be read along each

dimension

data OUT: Buffer for the image data

Purpose Reads a raster image.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description GRreadimage reads the subsample of the raster image specified by the parameter ri_id into the buffer data. The subsample is defined by the values of

the parameters *start*, *stride* and *edge*.

The array *start* specifies the starting location of the subsample to be read. Valid values of each element in the array *start* are 0 to the size of the corresponding raster image dimension - 1. The first element of the array *start* specifies an offset from the beginning of the array *data* along the fastest-changing dimension, which is the second dimension in C and the first dimension in Fortran. The second element of the array *start* specifies an offset from the beginning of the array *data* along the second fastest-changing dimension, which is the first dimension in C and the second dimension in Fortran. For example, if the first value of the array *start* is 2 and the second value is 3, the starting location of the subsample to be read is at the fourth row and third column in C, and at the third row and fourth column in Fortran.

The array *stride* specifies the reading pattern along each dimension. For example, if one of the elements of the array *stride* is 1, then every element along the corresponding dimension of the array *data* will be read. If one of the elements of the array *stride* is 2, then every other element along the corresponding dimension of the array *data* will be read, and so on. The correspondence between elements of the array *stride* and the dimensions of the array *data* is the same as described above for the array *start*.

Each element of the array *edges* specifies the number of data elements to be read along the corresponding dimension. The correspondence between the elements of the array *edges* and the dimensions of the array *data* is the same as described above for the array *start*.

Note that there are two FORTRAN-77 versions of this routine; one for numeric data (**mgrdimg**) and the other for character data (**mgrcimg**).

Note

Regarding an important difference between the SD and GR interfaces:

The SD and GR interfaces differ in the correspondence between the dimension order in parameter arrays such as *start*, *stride*, *edge*, and *dimsizes* and the dimension order in the *data* array. See the **SDreaddata** and **GRreadimage** reference manual pages for discussions of the SD and GR approaches, respectively.

When writing applications or tools to manipulate both images and twodimensional SDs, this crucial difference between the interfaces must be taken into account. While the underlying data is stored in row-major order in both cases, the API parameters are not expressed in the same way. Consider the example of an SD data set and GR image that are stored as identically-shaped arrays of X columns by Y rows and accessed via the **SDreaddata** and **GRreadimage** functions, respectively. Both functions take the parameters start, stride, and edge.

- For **SDreaddata**, those parameters are expressed in (y,x) or [row,column] order. For example, start[0] is the starting point in the Y dimension and start[1] is the starting point in the X dimension. The same ordering holds true for all SD data set manipulation functions.
- For **GRreadimage**, those parameters are expressed in (x,y) or [column,row] order. For example, start[0] is the starting point in the X dimension and start[1] is the starting point in the Y dimension. The same ordering holds true for all GR functions manipulating image data.

GRreadlut/mgrdlut/mgrclut

intn GRreadlut(int32 pal_id, VOIDP pal_data)

pal_id IN: Palette identifier returned by **GRgetlutid**

pal_data OUT: Buffer for the palette data

Purpose Reads a palette.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description GRreadlut reads the palette specified by the parameter pal_id into the buffer

pal_data.

Note that there are two FORTRAN-77 versions of this routine; one for numeric

data (mgrdlut) and the other for character data (mgrclut).

FORTRAN integer function mgrdlut(pal_id, pal_data)

integer pal_id

<valid numeric data type> pal_data(*)

integer function mgrclut(pal_id, pal_data)

integer pal_id

character*(*) pal_data

GRreftoindex/mgr2idx

int32 GRreftoindex(int32 gr_id, uint16 gr_ref)

gr_id IN: GR interface identifier returned by **GRstart**

 gr_ref IN: Reference number of the raster image

Purpose Maps the reference number of a raster image to an index.

Return value Returns the index of the image if successful and FAIL (or -1) otherwise.

Description GRreftoindex returns the index of the raster image specified by the parameter

gr_ref.

FORTRAN integer function mgr2idx(gr_id, gr_ref)

integer gr_id, gr_ref

GRreqimageil/mgrimil

intn GRreqimageil(int32 ri_id, intn interlace_mode)

ri id IN: Raster image identifier returned by **GRcreate** or **GRselect**

interlace_mode IN: Interlace mode

Purpose Specifies the interlace mode to be used in the subsequent raster image read

operation(s).

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description GRreqimageil requests that the subsequent read operations on the image identified by the parameter ri_id use the interlace mode specified by the

parameter interlace_mode.

The parameter *interlace_mode* specifies the interlace mode in which the data will be stored in memory when being read. Valid values of the parameter *interlace_mode* are MFGR_INTERLACE_PIXEL (or 0), MFGR_INTERLACE_LINE (or

1) and MFGR INTERLACE COMPONENT (or 2).

In the file, the image is always stored in pixel interlace mode, i.e. MFGR_INTERLACE_PIXEL. The interlace mode of the raster image specified at creation time is stored in the file along with the raster image. If **GRreqimageil** is not called prior to the call to **GRreadimage**, the raster image will be read and stored in memory according to the interlace mode specified at creation. If **GRreqimageil** is called before **GRreadimage**, **GRreadimage** will read the raster image and store it according to the interlace mode specified in the call to

GRreqimageil.

FORTRAN integer function mgrimil(ri_id, interlace_mode)

integer ri id, interlace mode

GRreqlutil/mgrltil

intn GRreqlutil(int32 *ri_id*, intn *interlace_mode*)

ri_id IN: Raster image identifier returned by **GRcreate** or **GRselect**

interlace_mode IN: Interlace mode

Purpose Specifies the interlace mode to be used in the next palette read operation(s).

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description GRreqlutil requests that the subsequent read operations on the palette attached

to the image identified by the parameter ri_id, use the interlace mode

interlace_mode.

The parameter *interlace_mode* specifies the interlace mode in which the data will be stored in memory when being read. Valid values of the parameter *interlace_mode* are MFGR_INTERLACE_PIXEL (or 0), MFGR_INTERLACE_LINE (or

1) and MFGR_INTERLACE_COMPONENT (or 2).

FORTRAN integer function mgrltil(ri_id, interlace_mode)

integer ri_id, interlace_mode

GRselect/mgselct

int32 GRselect(int32 gr_id, int32 index)

gr_id IN: GR interface identifier returned by **GRstart**

index IN: Index of the raster image in the file

Purpose Selects the existing raster image.

Return value Returns the raster image identifier if successful or FAIL (or -1) otherwise.

Description GRselect obtains the identifier of the raster image specified by the its index,

index.

Valid values of the parameter *index* range from 0 to the total number of raster images in the file - 1. The total number of the raster images in the file can be

obtained by using GRfileinfo.

FORTRAN integer function mgselct(gr_id, index)

integer gr_id, index

GRsetattr/mgsnatt/mgscatt

intn GRsetattr(int32 [obj]_id, char *attr_name, int32 data_type, int32 count, VOIDP values)

[obj]_id IN: Raster image identifier (ri_id), returned by **GRcreate** or **GRselect** or

GR interface identifier (gr_id) , returned by **GRstart**

attr name IN: Name of the attribute

data_type IN: Data type of the attribute

count IN: Number of values in the attribute

values IN: Buffer for the attribute values

Purpose Assigns an attribute to a raster image or a file.

Return value Returns Successful and FAIL (or -1) otherwise.

Description

GRsetattr attaches the attribute to the object specified by the parameter *obj_id*. The attribute is defined by its name, *attr_name*, data type, *data_type*, number of attribute values, *count*, and the attribute values, *values*. **GRsetattr** provides a generic way for users to define metadata. It implements the label = value data abstraction.

If an GR interface identifier (gr_id) is specified as the parameter obj_id , a global attribute is created which applies to all objects in the file. If a raster image identifier (ri_id) is specified as the parameter obj_id , an attribute is attached to the specified raster image.

The parameter *attr_name* can be any ASCII string.

The parameter *data_type* can contain any data type supported by the HDF library. These data types are listed in Table 1A in Section I of this manual.

Attribute values are passed in the parameter *values*. The number of attribute values is defined by the parameter *count*. If more than one value is stored, all values must have the same data type. If an attribute with the given name, data type and number of values exists, it will be overwritten. Currently, the only predefined attribute is the fill value, identified by the FILL_ATTR definition.

Note that there are two FORTRAN-77 versions of this routine; one for numeric data (**mgsnatt**) and the other for character data (**mgscatt**).

FORTRAN

<valid numeric data type> values(*)

GRsetcompress/mgscompress

intn GRsetcompress(int32 ri_id, int32 comp_type, comp_info *c_info)

ri_id IN: Raster image identifier returned by **GRcreate** or **GRselect**

comp_type IN: Compression method for the image data

C only:

c_info IN: Pointer to the comp_info union

Fortran only:

comp_prm IN: Compression parameters array

Purpose Specifies if the raster image will be stored in a file as a compressed raster

image.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description GRsetcompress specifies if the raster image specified by the parameter ri_id

will be stored in the file in compressed format.

The compression method is specified by the parameter *comp_type*. Valid values of the parameter *comp_type* are:

COMP CODE NONE (or 0) for no compression

COMP CODE RLE (or 1) for RLE run-length encoding

COMP_CODE_SKPHUFF (or 3) for Skipping Huffman compression

COMP_CODE_DEFLATE (or 4) for GZIP compression COMP_CODE_SZIP (or 5) for Szip compression COMP_CODE_JPEG (or 7) for JPEG compression

The compression method parameters are specified by the parameter c_info in C and the parameter $comp_prm$ in Fortran. The parameter c_info has type comp_info, which is described in the hcomp.h header file. It contains algorithm-specific information for the library compression routines.

The skipping size for the Skipping Huffman algorithm is specified in the field c_info.skphuff.skp_size in C and in the parameter $comp_prm(1)$ in Fortran.

The deflate level for the GZIP algorithm is specified in the field c info.deflate.level in C and in the parameter $comp_prm(1)$ in Fortran.

The parameter c_{info} is a pointer to a union structure of type comp_info. This union structure is defined as follows:

```
typedef union tag_comp_info
   struct
   /* Not used by GRsetcompress */
   } jpeg;
   struct
   /* Not used by GRsetcompress */
   } nbit;
   struct
    elements when skipping */
      intn skp_size;
   } skphuff;
   struct
    gzip encoded dataset how hard to work when compressing
      data*/
      intn level;
   } deflate;
    press
      szip encoded dataset*/
      int32 bits per pixel;
      int32 compression mode;
      int32 options_mask;
      int32 pixels;
      int32 pixels_per_block;
      int32 pixels per scanline;
   } szip;
} comp_info;
integer mgscompress(ri_id, comp_type, comp_prm)
integer ri_id, comp_type, comp_prm(*)
```

FORTRAN

GRsetchunk/mgschnk

intn GRsetchunk(int32 ri_id, HDF_CHUNK_DEF cdef, int32 flags)

ri_id IN: Raster image identifier returned by **GRcreate** or **GRselect**

C only:

cdef IN: Chunk definition

flags IN: Compression flags

Fortran only:

dim_length IN: Chunk dimensions array

comp_type IN: Type of compression

comp_prm IN: Compression parameters array

Purpose Makes a raster image a chunked raster image.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description

GRsetchunk makes the raster image specified by the parameter ri_id a chunked raster image according to the chunking and compression information provided in the parameters cdef and flags in C, or in the parameters $comp_type$ and $comp_prm$ in Fortran.

C only:

The parameter *cdef* is a union of type HDF_CHUNK_DEF, which is defined as follows:

Purpose

Makes a raster image a chunked raster image.

Valid values of the parameter *flags* are HDF_CHUNK for chunked and uncompressed data and (HDF_CHUNK | HDF_COMP) for chunked and compressed data. Data can be compressed using run-length encoding (RLE), Skipping Huffman or GZIP compression algorithms.

If the parameter *flags* has a value of HDF_CHUNK, the chunk dimensions must be specified in the field cdef.chunk_lengths[]. If the parameter *flags* has a value of (HDF_CHUNK | HDF_COMP), the following must be specified:

- 1) The chunk dimensions in the field cdef.comp.chunk lengths[].
- 2) The compression type in the field cdef.comp.comp_type. Valid values of compression type values are listed below.

COMP_CODE_NONE (or 0) for uncompressed data

 ${\tt COMP_CODE_RLE}$ (or 1) for data compressed using the RLE compression algorithm

COMP_CODE_SKPHUFF (or 3) for data compressed using the Skipping Huffman compression algorithm

COMP_CODE_DEFLATE (or 4) for data compressed using the GZIP compression algorithm

COMP_CODE_SZIP (or 5) for data compressed using the Szip compression algorithm

3) If using Skipping Huffman compression, the skipping size is specified in the field cdef.comp.cinfo.skphuff.skp_size. If using GZIP compression, the deflate level is specified in the field cdef.comp.cinfo.deflate.level. Valid deflate level values are integers from 1 to 9 inclusive.

Refer to the **SDsetcompress** page in this manual for the definition of the comp_info structure and for setting Szip compression parameters.

Fortran only:

The *dim_length* array specifies the chunk dimensions.

The parameter *comp_type* specifies the compression type. Valid compression types and their values used are defined in the hdf.inc file, and are listed below.

- COMP_CODE_NONE (or 0) for uncompressed data
- COMP_CODE_RLE (or 1) for data compressed using the RLE compression algorithm
- COMP_CODE_SKPHUFF (or 3) for data compressed using the Skipping Huffman compression algorithm
- COMP_CODE_DEFLATE (or 4) for data compressed using the GZIP compression algorithm.
- COMP_CODE_SZIP (or 5) for data compressed using the Szip compression algorithm.

The parameter *comp_prm* specifies the compression parameters for the Skipping Huffman and GZIP compression methods. It contains only one element which is set to the skipping size for Skipping Huffman compression or the deflate level for GZIP compression.

See the **SDsetcompress** reference manual entry for a description of the struct required with the use of Szip compression.

FORTRAN

integer function mgschnk(ri_id, dim_length, comp_type, comp_prm)

integer ri id, dim length, comp type, comp prm

GRsetchunkcache/mgscchnk

intn GRsetchunkcache(int32 ri_id, int32 maxcache, int32 flags)

ri_id IN: Raster image identifier returned by **GRcreate** or **GRselect**

maxcache IN: Maximum number of chunks to cache

flags IN: Flags determining the behavior of the routine

Purpose Specifies the maximum number of chunks to cache.

Return value Returns the value of the parameter *maxcache* if successful and FAIL (or -1)

otherwise.

Description GRsetchunkcache sets the maximum number of chunks to be cached for the

chunked raster image specified by the parameter ri_id . The maximum number

of the chunks is specified by the parameter *maxcache*.

Currently, the only valid value of the parameter *flags* is 0.

If **GRsetchunkcache** is not called, the maximum number of chunks in the cache is set to the number of chunks along the fastest-changing dimension. Refer to the discussion of the **GRsetchunkcache** routine in the *HDF User's*

Guide for more specific information on the routine's behavior.

FORTRAN integer function mgscchnk(ri_id, maxcache, flags)

integer ri_id, maxcache, flags

GRsetexternalfile/mgsxfil

intn GRsetexternalfile(int32 ri_id, char *filename, int32 offset)

ri_id IN: Raster image identifier returned by **GRcreate** or **GRselect**

filename IN: Name of the external file

offset IN: Offset in bytes from the beginning of the external file to where the

data will be written

Purpose Specifies that the raster image will be written to an external file.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description GRsetexternalfile specifies that the raster image identified by the parameter ri_id will be written to the external file specified by the parameter *filename* at

the offset specified by the parameter offset.

Data can only be moved once for any given raster image, and it is the user's responsibility to make sure the external data file is kept with the "original" file.

If the raster image already exists, its data will be moved to the external file. Space occupied by the data in the primary file will not be released. To release the space in the primary file use the hdfpack command-line utility. If the raster image does not exist, its data will be written to the external file during the subsequent calls to **GRwritedata**.

See the reference manual entries for **HXsetcreatedir** and **HXsetdir** for more information on the options available for accessing external files.

FORTRAN integer function mgsxfil(ri_id, filename, offset)

integer ri_id, offset
character*(*) filename

GRstart/mgstart

int32 GRstart(int32 file_id)

file_id IN: File identifier returned by **Hopen**

Purpose Initializes the GR interface.

Return value Returns the GR interface identifier if successful and FAIL (or -1) otherwise.

Description GRstart initializes the GR interface for the file specified by the parameter

file_id.

This routine is used with the **GRend** routine to define the extent of the GR interface session. As with the start routines in the other interfaces, **GRstart** initializes the internal interface structures needed for the remaining GR routines. Use the general purpose routines **Hopen** and **Hclose** to manage file

access. The GR routines will not open and close HDF files.

FORTRAN integer function mgstart(file_id)

integer file_id

GRwritechunk/mgwchnk/mgwcchnk

intn GRwritechunk(int32 ri_id, int32 *origin, const VOIDP datap)

ri_id IN: Raster image identifier returned by **GRcreate** or **GRselect**

origin IN: Origin of the chunk to be written

datap IN: Buffer for the chunk to be written

Purpose Writes a data chunk to a chunked raster image (pixel-interlace only)

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

GRwritechunk returns FAIL (or -1) when an attempt is made to use it to write

to a non-chunked raster image.

Description GRwritechunk writes the entire chunk of data stored in the buffer *datap* to the

chunked raster image identified by the parameter ri_id . Writing starts at the location specified by the parameter origin. This function has less overhead than **GRwriteimage** and should be used whenever an entire chunk of data is to

be written.

The parameter *origin* is a two-dimensional array which specifies the coordinates of the chunk according to the chunk position in the overall chunk array. Refer to Chapter 8, "General Raster Images (GR API)," in the *HDF*

User's Guide.

The *datap* buffer contains the chunk's data organized in a pixel interlace mode.

FORTRAN integer mgwchnk(ri_id, origin, datap)

integer ri_id, origin(2)

<valid_numeric_datatype> datap(*)

integer mgwcchnk(ri_id, origin, char_datap)

integer ri_id, origin(2)

character*(*) char_datap

start

GRwriteimage/mgwrimg/mgwcimg

intn GRwriteimage(int32 ri_id, int32 start[2], int32 stride[2], int32 edge[2], VOIDP data)

ri_id IN: Raster image identifier returned by **GRcreate** or **GRselect**

IN: Array containing the two-dimensional coordinate of the initial

location for the write

stride IN: Array containing the number of data locations the current location is

to be moved forward before each write

edge IN: Array containing the number of data elements that will be written

along each dimension

data IN: Buffer containing the image data

Purpose Writes a raster image.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description GRwriteimage writes the subsample of the raster image data stored in the buffer data to the raster image specified by the parameter ri_id . The subsample

is defined by the values of the parameters *start*, *stride* and *edge*.

The array *start* specifies the starting location of the subsample to be written. Valid values of each element in the array *start* are 0 to the size of the corresponding raster image dimension - 1. The first element of the array *start* specifies an offset from the beginning of the array *data* along the fastest-changing dimension, which is the second dimension in C and the first dimension in Fortran. The second element of the array *start* specifies an offset from the beginning of the array *data* along the second fastest-changing dimension, which is the first dimension in C and the second dimension in Fortran. For example, if the first value of the array *start* is 2 and the second value is 3, the starting location of the subsample to be written is at the fourth row and third column in C, and at the third row and fourth column in Fortran.

The array *stride* specifies the writing pattern along each dimension. For example, if one of the elements of the array *stride* is 1, then every element along the corresponding dimension of the array *data* will be written. If one of the elements of the *stride* array is 2, then every other element along the corresponding dimension of the array *data* will be written, and so on. The correspondence between elements of the array *stride* and the dimensions of the array *data* is the same as described above for the array *start*.

Each element of the array *edges* specifies the number of data elements to be written along the corresponding dimension. The correspondence between the elements of the array *edges* and the dimensions of the array *data* is the same as described above for the array *start*.

Note that there are two FORTRAN-77 versions of this routine; one for numeric data (**mgwrimg**) and the other for character data (**mgwcimg**).

Note

Regarding an important difference between the SD and GR interfaces:

The SD and GR interfaces differ in the correspondence between the dimension order in parameter arrays such as *start*, *stride*, *edge*, and *dimsizes* and the dimension order in the *data* array. See the **SDreaddata** and **GRreadimage** reference manual pages for discussions of the SD and GR approaches, respectively.

When writing applications or tools to manipulate both images and twodimensional SDs, this crucial difference between the interfaces must be taken into account. While the underlying data is stored in row-major order in both cases, the API parameters are not expressed in the same way. Consider the example of an SD data set and GR image that are stored as identically-shaped arrays of X columns by Y rows and accessed via the **SDreaddata** and **GRreadimage** functions, respectively. Both functions take the parameters start, stride, and edge.

- For **SDreaddata**, those parameters are expressed in (y,x) or [row,column] order. For example, start[0] is the starting point in the Y dimension and start[1] is the starting point in the X dimension. The same ordering holds true for all SD data set manipulation functions.
- For **GRreadimage**, those parameters are expressed in (x,y) or [column,row] order. For example, start[0] is the starting point in the X dimension and start[1] is the starting point in the Y dimension. The same ordering holds true for all GR functions manipulating image data.

```
FORTRAN
```

```
integer function mgwrimg(ri_id, start, stride, edge, data)
integer ri_id, start(2), stride(2), edge(2)

integer ri_id, start(2), stride(2), edge(2)
character*(*) data
```

GRwritelut/mgwrlut/mgwclut

intn GRwritetlut(int32 pal_id, int32 ncomp, int32 data_type, int32 interlace_mode, int32 num_entries, VOIDP pal_data)

pal_id IN: Palette identifier returned by **GRgetlutid**

ncomp IN: Number of components in the palette

data_type IN: Data type of the palette data

interlace_mode IN: Interlace mode of the stored palette data

num_entries IN: Number of entries in the palette

pal_data IN: Buffer for the palette data to be written

Purpose Writes a palette.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description

GRwritelut writes a palette with the number of pixel components specified by the parameter *ncomp*, the data type of the palette data specified by the parameter *data_type*, the interlace mode specified by the parameter *interlace_mode*, and the number of entries in the palette specified by the parameter *num_entries*. The palette data itself is stored in the *pal_data* buffer. **Currently only "old-style" palettes are supported**, i.e *ncomp* = 3, *num_entries* = 256, *data_type* = *uint8*.

The parameter *ncomp* specifies the number of pixel components in the palette and must have a value of at least 1.

The parameter *data_type* specifies the type of the palette data and can be any of the data types supported by the HDF library. The data types supported by HDF are listed in Table 1A in Section I of this manual.

The parameter *interlace_mode* specifies the interlacing in which the palette is to be written. The valid values of *interlace_mode* are: MFGR_INTERLACE_PIXEL (or 0), MFGR_INTERLACE_LINE (or 1) and MFGR_INTERLACE_COMPONENT (or 2).

The buffer *pal_data* is assumed to have sufficient space allocated to store all of the palette data.

Note that there are two FORTRAN-77 versions of this routine; one for numeric data (**mgwrlut**) and the other for character data (**mgwclut**).

FORTRAN

integer pal_id, ncomp, data_type, interlace_mode, num_entries
<valid numeric data type> pal data(*)

integer pal_id, ncomp, data_type, interlace_mode, num_entries
character*(*) pal_data

HDF Reference Manual Hclose/hclose

Hclose/hclose

intn Hclose(int32 file_id)

file_id IN: File identifier returned by **Hopen**

Purpose Closes the access path to the file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description The file identifier *file_id* is validated before the file is closed. If the identifier is

valid, the function closes the access path to the file.

If there are still access identifiers attached to the file, the error DFE_OPENAID is placed on the error stack, FAIL (or -1) is returned, and the file remains open. This is a common error when developing new interfaces. Refer to the Reference Manual page on **Hendaccess** for a discussion of this problem.

FORTRAN integer function hclose(file_id)

integer file_id

Hgetfileversion/hgfilver

intn Hgetfileversion(int32 file_id, uint32 *major_v, uint32 *minor_v, uint32 *release, char string[])

file_id IN: File identifier returned by **Hopen**

major_v OUT: Major version number

minor_v OUT: Minor version number

release OUT: Release number

string OUT: Version number text string

Purpose Retrieves version information for an HDF file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description It is still an open question as to what exactly the version number of a file

should mean, so we recommend that code not depend on this buffer. The *string* argument is limited to a length of LIBVSTR_LEN (or 80) characters as defined

in hfile.h.

FORTRAN integer function hgfilver(file_id, major_v, minor_v, release, string)

integer file_id, major_v, minor_v, release

character*(*) string

Hgetlibversion/hglibver

intn Hgetlibversion(uint32 *major_v, uint32 *minor_v, uint32 *release, char string[])

major_v OUT: Major version number

minor_v OUT: Minor version number

release OUT: Release number

string OUT: Version number text string

Purpose Retrieves the version information of the current HDF library.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description The version information is compiled into the HDF library, so it is not necessary

to have any open files for this function to execute. The string buffer is limited

to a length of LIBVSTR_LEN (or 80) characters as defined in hfile.h.

FORTRAN integer function hglibver(major_v, minor_v, release, string)

integer major_v, minor_v, release

character*(*) string

Hishdf/hishdff

intn Hishdf(char *filename)

IN: filename Complete path and filename of the file to be checked

Purpose Determines if a file is an HDF file.

Returns TRUE (or 1) if the file is an HDF file and FALSE (or 0) otherwise. Return value

The first four bytes of a file identify it as an HDF file. It is possible that **Hishdf** will identify a file as an HDF file but **Hopen** will be unable to open the file; for Description

example, if the data descriptor list is corrupt.

Fortran integer function hishdff(filename)

character*(*) filename

Hopen/hopen

int32 Hopen(char *filename, intn access, int16 n_dds)

filename IN: Complete path and filename for the file to be opened

access IN: Access code definition (preceded by DFACC_)

 $n_{\perp}dds$ IN: Number of data descriptors in a block if a new file is to be created

Purpose Provides an access path to an HDF file by reading all the data descriptor blocks

into memory.

Return value Returns the file identifier if successful and FAIL (or -1) otherwise.

Description If given a new file name, **Hopen** will create a new file using the specified access type and number of data descriptors. If given an existing file name, **Hopen** will open the file using the specified access type and ignore the n_dds

argument.

The number of data descriptors in a block, n_dds , is a non-negative integer with a default value of <code>DEF_NDDS</code> (or 16) and a minimum value of <code>MIN_NDDS</code> (or 4). If the specified value of n_dds is less than <code>MIN_NDDS</code>, then it will be set to <code>MIN_NDDS</code>.

HDF provides several access code definitions:

DFACC_CREATE If file exists, delete it, then open a new file for read/write.

DFACC_READ Open for read only. If file does not exist, error.

DFACC_WRITE Open for read/write. If file does not exist, create it.

If a file is opened and an attempt is made to reopen the file using DFACC_CREATE, HDF will issue the error code DFE_ALROPEN. If the file is opened with read-only access and an attempt is made to reopen the file for write access using DFACC_WRITE, HDF will attempt to reopen the file with read and write permissions.

Upon successful exit, the specified file is opened with the relevant permissions, the data descriptors are set up in memory, and the associated *file_id* is returned. For new files, the appropriate file headers are also set up.

FORTRAN integer function hopen(filename, access, n_dds)

character*(*) filename
integer access, n_dds

HCgetcompress

intn HCgetcompress(int32 access_id, comp_coder_t *comp_type, comp_info *c_info)

access id IN: Access record identifier

comp_type OUT: Type of compression

c_info OUT: Pointer to compression information structure

Purpose Retrieves data compression type and information for specified element.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description HCgetcompress retrieves the compression type and compression information for the element specified by *access_id*.

The compression method is returned in the parameter cown type

The compression method is returned in the parameter *comp_type*. Valid values of *comp_type* are as follows:

COMP_CODE_NONE (or 0) for no compression

COMP_CODE_RLE (or 1) for RLE run-length encoding

COMP_CODE_NBIT (or 2) for NBIT compression

COMP_CODE_SKPHUFF (or 3) for Skipping Huffman compression

COMP_CODE_DEFLATE (or 4) for GZIP compression

COMP_CODE_JPEG (or 6) for JPEG compression

The compression method parameters are returned in the c_info struct in C and the array parameter $comp_prm$ in Fortran. The c_info struct is of type comp_info, contains algorithm-specific information for the library compression routines, and is described in the hcomp.h header file.

HCgetcompress is used by GRgetcompress and SDgetcompress.

Note regarding HDF4 Release 2.0 beta: Szip compression has been added to the HDF4 library for Release 2.0. That addition is documented in the **GRsetcompress** and **GRgetcompress** reference manual entries but is not yet reflected here.

HDdont_atexit/hddontatexit

intn HDdont_atexit(void)

Purpose Indicates to the library that an 'atexit()' routine is _not_ to be installed.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description This routine indicates to the library that an atexit() cleanup routine

should not be installed. The purpose for this is in situations where the library is dynamically linked into an application and is unlinked from the application before exit() gets called. In those situations, a routine installed with atexit() would jump to a routine which was no longer in memory,

causing errors.

In order to be effective, this routine *must* be called before any other HDF function calls, and *must* be called each time the library is loaded/linked into the

application (the first time and after it has been unloaded).

If this routine is used, certain memory buffers will not be deallocated,

although in theory a user could call **HPend** on their own.

FORTRAN integer hddontatexit()

HEprint/heprntf/heprnt

VOID HEprint(FILE *stream, int32 level)

stream IN: Stream to print error message to

level IN: Level of error stack to print

Purpose Prints information to the error stack.

Return value None.

Fortran runction returns 0 (zero) on success or -1 on failure.

Description If *level* is 0, all of the errors currently on the error stack are printed. Output

from this function is sent to the file pointed to by *stream*.

The following information is printed: the ASCII description of the error, the reporting routine, the reporting routine as source file name, and the line at which the error was reported. If the programmer has supplied extra information by means of **HEreport**, this information is printed as well.

by means of **Hereport**, this information is printed as wen.

The FORTRAN-77 routine **heprnt** uses one less parameter than the C routine because it doesn't allow the user to specify the print stream. Instead, it always

prints to stdout.

The FORTRAN-77 routine **heprntf** is available on all platforms; **heprnt** is not supported on Microsoft Windows platforms.

The **heprntf** parameter *filename* is the name of the file to which error output is to be written. If the value of *filename* is an empty string (''), error output will be written to standard output, stdout.

FORTRAN integer function heprntf(filename, level)

character*(*) filename

integer level

integer function heprnt(level)

integer level

HEstring/hestringf

const char *HEstring(hdf_err_code_t error_code)

error_code IN: HDF error code

Purpose Returns the error message associated with specified error code.

Return value Returns a pointer to a string associated with the error code if successful.

Description Returns a text description of the given error code. These strings are statically

declared and should not be deallocated from memory (using the free routine) by the user. If a defined text description cannot be found a generic default

message is returned.

FORTRAN integer function hestringf(error_code, error_message)

integer error_code

character*(*) error_message

HXsetcreatedir/hxiscdir

intn HXsetcreatedir(char *dir)

dir IN: Target directory of the external file to be written

Purpose Initializes the directory environment variable, identifying the location of the

external file to be written.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description The contents of *dir* is copied into the private memory of the HDF library. If *dir*

is NULL, the directory variable is unset. If **HXsetcreatedir** encounters an error condition, the directory variable is not changed. When a new external element is created (via the routines **HXcreate** or **SDsetexternal**), the HDF library accesses the external file just like the **open** call by default. Refer to the Reference Manual page on **HXcreate** for a description of when a new or an old

file should be opened.

Users may override the default action by calling **HXsetcreatedir** or by defining the environment variable \$HDFEXTCREATEDIR. The HDF library will access the external file in the directory according to the environment variable setting. The precedence is **HXsetcreatedir**, then \$HDXEXTDIR, in the manner of

open.

Note that the above override does not apply to absolute pathnames - i.e., filenames starting with a forward slash. HDF will access the absolute pathname without change. Also note that **HXsetcreatedir** and \$HDFEXTCREATEDIR are not symmetrical to **HXsetdir** and \$HDFEXTDIR. The former pair permits only single directory values and is used to compose the filename for access. The later pair permits multiple directory values which are used for searching an existing file.

The *dir_len* parameter in the FORTRAN-77 routine specifies the length of the *dir* character string.

FORTRAN integer function hxiscdir(dir, dir_len)

character*(*) dir

integer dir_len

HXsetdir/hxisdir

intn HXsetdir(char *dir)

dir IN: Target directory of the external file to be located

Purpose Initializes the directory environment variable, identifying the location of the

external file to be located.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description HXsetdir sets the directory variable for locating an external file according to *dir* which may contain multiple directories separated by vertical bars (e.g., "dir1ldir2"). The content of *dir* is copied into the private memory of the HDF library. If *dir* is NULL, the directory variable is unset.

If **HXsetdir** encounters any error, the directory variable is not changed. By default, the HDF library locates the external file just like the **open** call. It also searches for the external file in the directories specified by the user environment variable \$HDFEXTDIR, if defined, and the directory variable set by **HXsetdir**. The searching precedence is directory variable, if set, then \$HDXEXTDIR, then in the manner of **open**.

The searching differs if the external filename is an absolute pathname - i.e., starting with a forward slash. HDF will try **open** first. If **open** fails and if \$HDFEXTDIR is defined or the directory variable is set via **HXsetdir**, HDF will remove all directory components of the absolute pathname (e.g., "/usr/groupA/projectB/Data001" becomes "Data001") and search for that filename with the strategy described in the previous paragraph.

The *dir_len* parameter in the FORTRAN-77 routine specifies the length of the *dir* character string.

FORTRAN integer function hxisdir(dir, dir_len)

character*(*) dir
integer dir_len

SDattrinfo/sfgainfo

intn SDattrinfo(int32 obj_id, int32 attr_index, char *attr_name, int32 *data_type, int32 *count)

obj_id IN: Identifier of the object to which the attribute is attached to

attr_index IN: Index of the attribute

attr_name OUT: Name of the attribute

data_type OUT: Data type of the attribute values

count OUT: Total number of values in the attribute

Purpose Retrieves information about an attribute.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description SDattrinfo retrieves the name, data type, and number of values of the attribute

specified by its index, attr_index, and stores them in the parameters attr_name, data_type, and count, respectively. This routine should be used

before reading the values of an attribute with **SDreadattr**.

The parameter *obj_id* can be either an SD interface identifier (*sd_id*), returned by **SDstart**, a data set identifier (*sds_id*), returned by **SDselect**, or a dimension

identifier (dim_id), returned by **SDgetdimid**.

Valid values of the parameter attr_index range from 0 to the number of

attributes attached to the object - 1.

Valid values of the parameter data_type can be found in Table 1A of Section I

of this manual.

FORTRAN integer function sfgainfo(obj_id, attr_index, attr_name, data_type, count)

character*(*) attr_name

integer obj_id, attr_index, data_type, count

SDcheckempty/sfchempty

int32 SDcheckempty(int32 sds_id, intn *emptySDS)

sds_id IN: SDS identifier

emptySDS OUT: Boolean value indicating whether the SDS is empty

Purpose Determines whether a scientific dataset (an SDS) is empty.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description SDcheckempty sets the parameter *emptySDS* to TRUE if the dataset identified

by sds_id has not been written with data, and to FALSE, otherwise.

The Fortran routine, sfchempty, returns 1 in emptySDS if the dataset is empty

and 0 otherwise.

FORTRAN integer function sfchempty(sds_id, emptySDS)

integer sds_id, emptySDS

SDcreate/sfcreate

int32 SDcreate(int32 sd_id, char *name, int32 data_type, int32 rank, int32 dimsizes[])

sd_id IN: SD interface identifier returned by SDstart

name IN: Name of the data set

data_type IN: Data type for the values in the data set

rank IN: Number of the data set dimensions

dimsizes IN: Array containing the size of each dimension

Purpose Creates a new data set.

Return value Returns the data set identifier (*sds_id*) if successful and FAIL (or -1) otherwise.

SDcreate creates a data set with the name specified by the parameter *name*, the values of the data type specified by parameter *data_type*, the number of dimensions specified by the parameter *rank*, and the dimension sizes specified by the array *dimsizes*.

Once a data set has been created, it is not possible to change its name, data type, or rank. However, it is possible to create a data set and close the file before writing any data values to it. The values can be added or modified at a future time. To add data or modify an existing data set, use **SDselect** to get the data set identifier instead of **SDcreate**.

If the parameter *name* is NULL in C or an empty string in Fortran, the default name "Data Set" will be generated. The length of the name specified by the *name* parameter must be 63 characters or less.

- If the length of the name is longer than 63 characters but less than or equal to MAX_NC_NAME characters (256 characters by default), then the name will be truncated to 63 characters.
- If the length of the name is longer than MAX_NC_NAME characters (256 characters by default), then **SDcreate** will fail.

The calling program must ensure that the length of the *dimsizes* array is the value of the *rank* parameter, which is between 1 and MAX_VAR_DIMS (or 32).

To create a data set with an unlimited dimension, assign the value of SD_UNLIMITED (or 0) to dimsizes[0] in C and to dimsizes(rank) in Fortran.

The *data_type* parameter can contain any data type supported by the HDF library. These data types are listed in Table 1A in Section I of this manual.

See the notes regarding the potential performance impact of unlimited dimension data sets in the *HDF User's Guide* Section 14.4.3, "Unlimited Dimension Data Sets (SDSs and Vdatas) and Performance."

Note

Regarding an important difference between the SD and GR interfaces:

The SD and GR interfaces differ in the correspondence between the dimension order in parameter arrays such as *start*, *stride*, *edge*, and *dimsizes* and the dimension order in the *data* array. See the **SDreaddata** and **GRreadimage** reference manual pages for discussions of the SD and GR approaches, respectively.

When writing applications or tools to manipulate both images and two-dimensional SDs, this crucial difference between the interfaces must be taken into account. While the underlying data is stored in row-major order in both cases, the API parameters are not expressed in the same way. Consider the example of an SD data set and GR image that are stored as identically-shaped arrays of X columns by Y rows and accessed via the **SDreaddata** and **GRreadimage** functions, respectively. Both functions take the parameters *start*, *stride*, and *edge*.

- For **SDreaddata**, those parameters are expressed in (y,x) or [row,column] order. For example, start[0] is the starting point in the Y dimension and start[1] is the starting point in the X dimension. The same ordering holds true for all SD data set manipulation functions.
- For **GRreadimage**, those parameters are expressed in (x,y) or [column,row] order. For example, start[0] is the starting point in the X dimension and start[1] is the starting point in the Y dimension. The same ordering holds true for all GR functions manipulating image data

FORTRAN

```
character*(*) name
```

integer sd_id, data_type, rank, dimsizes(*)

SDdiminfo/sfgdinfo

intn SDdiminfo(int32 dim_id, char *name, int32 *size, int32 *data_type, int32 *num_attrs)

dim_id IN: Dimension identifier returned by **SDgetdimid**

name OUT: Name of the dimension

size OUT: Size of the dimension

data_type OUT: Data type of the dimension scale

num_attrs OUT: Number of attributes assigned to the dimension

Purpose Retrieves information about a dimension.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description SDdiminfo retrieves the name, size, data type, and number of values of the dimension specified by the parameter dim_id , and stores them in the

parameters *name*, *size*, *data_type*, and *num_attrs*, respectively.

If the output value of the parameter *size* is set to 0, then the dimension specified by the *dim_id* parameter is unlimited. To get the number of records of

an unlimited dimension, use **SDgetinfo**.

If scale information has been stored for this dimension via **SDsetdimscale**, the *data_type* parameter will contain the data type. Valid data types can be found in Table 1A of Section I of this manual. If no scale information has been stored for this dimension, the value returned in the *data_type* parameter will be 0.

If the user has not named the dimension via **SDsetdimname**, a default dimension name of "fakeDim[x]" will be generated by the library, where [x] denotes the dimension index. If the name is not desired, the parameter *name* can be set to NULL in C and an empty string in Fortran.

FORTRAN

character*(*) name

integer dim_id, size, data_type, num_attrs

SDend/sfend

intn SDend(int32 sd_id)

sd_id IN: SD interface identifier returned by SDstart

Purpose Terminates access to an SD interface.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description SDend closes the file and frees memory allocated by the library when SD

interface activities are completed. If the calling program exits without invoking this routine, recent changes made to the in-core file data are likely not to be flushed to the file. Note that each **SDstart** must have a matching **SDend**.

FORTRAN integer function sfend(sd_id)

integer sd_id

SDendaccess/sfendacc

intn SDendaccess(int32 sds_id)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

Purpose Terminates access to a data set.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description SDendaccess frees the memory taken up by the HDF library's data structures

devoted to the data set identified by the parameter *sds_id*.

Failing to call this routine after all operations on the specified data set are complete may result in loss of data. This routine must be called once for each

call to SDcreate or SDselect.

FORTRAN integer function sfendacc(sds_id)

integer sds_id

SDfileinfo/sffinfo

intn SDfileinfo(int32 sd_id, int32 *num_datasets, int32 *num_global_attrs)

sd id IN: SD interface identifier returned by **SDstart**

num_datasets OUT: Number of data sets in the file

num_global_attrs OUT: Number of global attributes in the file

Purpose Retrieves the number of data sets and the number of global attributes in a file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description SDfileinfo returns the number of data sets in the parameter *num_datasets* and

the number of global attributes in the parameter num_global_attrs. The term "global attributes" refers to attributes that are assigned to the file. The global attributes are created by **SDsetattr** using an SD interface identifier (sd_id)

rather than a data set identifier (sds_id).

The value returned by the parameter *num_datasets* includes the number of coordinate variable data sets. To determine if the data set is a coordinate

variable, use SDiscoordvar.

FORTRAN integer function sffinfo(sd_id, num_datasets, num_global_attrs)

integer sd_id, num_datasets, num_global_attrs

SDfindattr/sffattr

int32 SDfindattr(int32 *obj_id*, char **attr_name*)

obj_id IN: Identifier of the object to which the attribute is attached

attr_name IN: Name of the attribute

Purpose Finds the index of an attribute given its name.

Return value Returns the index if successful and FAIL (or -1) otherwise.

Description SDfindattr retrieves the index of the object's attribute with the name specified

by the parameter *attr_name*.

The attribute is attached to the object specified by the parameter *obj_id*. The parameter *obj_id* can be either an SD interface identifier (*sd_id*), returned by **SDstart**, a data set identifier (*sds_id*), returned by **SDselect**, or a dimension

identifier (dim_id), returned by **SDgetdimid**.

Wildcard characters are not allowed in the parameter *attr_name*. **SDfindattr** searches for the name specified in the parameter *attr_name* in a case-sensitive

manner.

FORTRAN integer function sffattr(obj_id, attr_name)

integer obj_id

character*(*) attr_name

SDgetcal/sfgcal

intn SDgetcal(int32 sds_id, float64 *cal, float64 *cal_err, float64 *offset, float64 *offset_err, int32 *data_type)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

cal OUT: Calibration factor

cal_err OUT: Calibration error

offset OUT: Uncalibrated offset

offset_err OUT: Uncalibrated offset error

data_type OUT: Data type of uncalibrated data

Purpose Retrieves the calibration information associated with a data set.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description

SDgetcal reads the calibration record attached to the data set identified by the parameter *sds_id*. A calibration record is comprised of four 64-bit floating point values followed by a 32-bit integer. The information is listed in the following table:

cal	calibration factor
cal_err	calibration error
offset	uncalibrated offset
offset_err	uncalibrated offset error
data_type	data type of the uncalibrated data

The relationship between a calibrated value cal_value and the original value orig_value is defined as orig_value = cal * (cal_value - offset).

The variable offset_err contains a potential error of offset, and cal_err contains a potential error of cal. Currently the calibration record is provided for information only. The SD interface performs no operations on the data based on the calibration tag.

FORTRAN

integer sds_id, data_type

real*8 cal, cal_err, offset, offset_err

SDgetchunkinfo/sfgichnk

intn SDgetchunkinfo(int32 sds_id, HDF_CHUNK_DEF *cdef, int32 *flag)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

C only:

cdef OUT: Pointer to the chunk definition

flag OUT: Compression flag

Fortran only:

dim_length OUT: Array of chunk dimensions

flag OUT: Compression flag

Purpose Retrieves chunking information for a data set.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description

SDgetchunkinfo retrieves chunking information about the data set identified by the parameter *sds_id* into the parameters *cdef* and *flag* in C, and to the parameters *dim_length* and *flag* in Fortran.

Currently, only information about chunk dimensions is retrieved into the corresponding *cdef* structure element for each type of compression in C, and in the *dim_length* array in Fortran. No information on compression parameters is available in the comp structure of the HDF_CHUNK_DEF union. Refer to the page on **SDsetchunk** in this manual for specific information on the HDF_CHUNK_DEF union.

The value returned in the *flag* parameter indicates the data set type (i.e., if the data set is not chunked, chunked, and chunked and compressed).

If the chunk length for each dimension is not needed, NULL can be passed in as the value of the *cdef* parameter in C.

The following table shows the type of the data set, possible values of the *flag* parameter, and the corresponding *cdef* structure element filled with the chunk's dimensions.

Type of Data Set	Values of <i>flag</i> in C (Fortran)	cdef Structure Element Filled with the Chunk's Dimensions
Not chunked	HDF_NONE (-1)	None
Chunked	HDF_CHUNK (0)	cdef.chunk_lengths[]

Type of Data Set	Values of <i>flag</i> in C (Fortran)	cdef Structure Element Filled with the Chunk's Dimensions
Chunked and compressed with either the run-length encoding (RLE), Skipping Huffman or GZIP compression algorithms	HDF_CHUNK HDF_COMP (1)	cdef.comp.chunk_lengths[]
Chunked and compressed with NBIT compression	HDF_CHUNK I HDF_NBIT (2)	cdef.nbit.chunk_lengths[]

FORTRAN integer function sfgichnk(sds_id, dim_length, flag)

integer sds_id, dim_length(*), flag

SDgetcompress/sfgcompress

intn SDgetcompress(int32 sds_id, comp_coder_t *comp_type, comp_info *c_info)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

comp_type OUT: Type of compression

c_info OUT: Pointer to compression information structure

Purpose Retrieves data set compression type and compression information.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description SDgetcompress retrieves the compression type and compression information for a data set.

The compression method is returned in the parameter *comp_type*. Valid values of *comp_type* are as follows:

```
COMP_CODE_NONE (or 0) for no compression
COMP_CODE_RLE (or 1) for RLE run-length encoding
COMP_CODE_NBIT (or 2) for NBIT compression
COMP_CODE_SKPHUFF (or 3) for Skipping Huffman compression
COMP_CODE_DEFLATE (or 4) for GZIP compression
```

Additional compression method parameters are returned in the *c_info* struct in C and the array parameter *comp_prm* in Fortran. Note that *c_info* and *comp_prm* come into play only with compression modes that require additional parameters (i.e., other that *comp_type*); they are ignored in other cases.

The c_i nfo struct is of type comp_info, contains algorithm-specific information for the library compression routines, and is described in the hoomp.h header file.

The *comp_prm* parameter is an array returning one or more parameters, as required by the compression method in use. Each compression parameter is returned as an element of the array, as follows:

- With Skipping Huffman compression, comp_prm is a 1-element array and comp_prm(1) contains the skip value, skphuff_skp_size.
- In the case of GZIP compression, *comp_prm* is also a 1-element array and *comp_prm(1)* contains the deflation value, *deflate_value*.
- In the case of NBIT compression, comp_prm is a 4-element array with sign_ext in comp_prm(1), fill_one in comp_prm(2), start_bit in comp_prm(3), and bit_len in comp_prm(4). sign_ext, fill_one, start_bit, and bit_len are discussed in the SDsetnbitdataset/sfsnbit entry of the reference manual.

```
FORTRAN integer function sfgcompress(sds_id, comp_type, comp_prm)

integer sds_id, comp_type, comp_prm(*)
```

SDgetdatastrs/sfgdtstr

intn SDgetdatastrs(int32 sds_id, char *label, char *unit, char *format, char *coordsys, intn length)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

label OUT: Label (predefined attribute)

unit OUT: Unit (predefined attribute)

format OUT: Format (predefined attribute)

coordsys OUT: Coordinate system (predefined attribute)

length IN: Maximum length of the above predefined attributes

Purpose Retrieves the predefined attributes of a data set.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description SDgetdatastrs retrieves the predefined attributes for the data set specified by

the parameter *sds_id*. The predefined attributes are label, unit, format, and coordinate system. They are then stored in the parameters *label*, *unit*, *format*, and *coordsys*, respectively. Refer to Section 3.10 of the HDF User's Guide for

more information on predefined attributes.

If a particular data string is not stored, the first character of the corresponding **SDgetdatastrs** parameter is '\0' in C. In FORTRAN, the parameter contains an empty string. Each string buffer must include the space to hold the null termination character. In C, if a user does not want a string back, NULL can be passed in for that string. Data strings are set by the **SDsetdatastrs** routine.

FORTRAN integer function sfgdtstr(sds_id, label, unit, format, coordsys,

integer sds_id, length

character*(*) label, unit, format, coordsys

SDgetdimid/sfdimid

int32 SDgetdimid(int32 sds_id, intn dim_index)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

dim_index IN: Index of the dimension

Purpose Returns the identifier of a dimension given its index.

Return value Returns the dimension identifier (dim_id) if successful and fail (or -1)

otherwise.

Description SDgetdimid returns the identifier of the dimension specified by its index, the

parameter *dim_index*.

The dimension index is a nonnegative integer and is less than the total number

of data set dimensions returned by SDgetinfo.

FORTRAN integer function sfdimid(sds_id, dim_index)

integer sds_id, dim_index

SDgetdimscale/sfgdscale

intn SDgetdimscale(int32 dim_id, VOIDP scale_buf)

dim_id IN: Dimension identifier returned by **SDgetdimid**

scale_buf OUT: Buffer for the scale values

Purpose Retrieves the scale values for a dimension.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

SDgetdimscale retrieves the scale values of the dimension identified by the parameter *dim id* and stores the values in the buffer *scale buf*.

SDdiminfo should be used to determine whether a scale has been set for the dimension, i.e., that the dimension scale data type is a valid HDF data type (not 0). Also use **SDdiminfo** to obtain the number of scale values for space allocation before calling **SDgetdimscale**.

It is not possible to read a subset of the scale values. **SDgetdimscale** returns all of the scale values stored with the given dimension.

The fact that **SDgetdimscale** returns SUCCEED should not be interpreted to mean that scale values have been defined for the data set. This function should always be used with **SDdiminfo**, which is used first to determine whether a scale has been set, the number of scale values, their data type, etc. If **SDdiminfo** indicates that no scale values have been set, the values returned by **SDgetdimscale** in data should be ignored.

FORTRAN integer function sfgdscale(dim_id, scale_buf)

integer dim id

<valid numeric data type> scale_buf(*)

SDgetdimstrs/sfgdmstr

intn SDgetdimstrs(int32 dim_id, char *label, char *unit, char *format, intn length)

dim_id IN: Dimension identifier returned by **SDgetdimid**

label OUT: Label (predefined attribute)

unit OUT: Unit (predefined attribute)

format OUT: Format (predefined attribute)

length IN: Maximum length of the above predefined attributes

Purpose Retrieves the predefined attributes of a dimension.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description SDgetdimstrs retrieves the predefined attributes associated with the dimension

identified by the parameter *dim_id*. The predefined attributes are label, unit, and format. These predefined attributes are stored in the parameters *label*, *unit*, and *format*, respectively. Refer to Section 3.10 of the HDF User's Guide

for more information on predefined attributes.

If a particular data string was not stored, the first character of the corresponding **SDgetdimstrs** parameter is '\0'. Each string buffer must include space for the null termination character. If a user does not want a string returned, the corresponding parameter can be set to NULL in C and an empty

string in Fortran. The predefined attributes are set by **SDsetdimstrs**.

FORTRAN integer function sfgdmstr(dim_id, label, unit, format, length)

integer dim_id, length

character*(*) label, unit, format

SDgetfillvalue/sfgfill/sfgcfill

intn SDgetfillvalue(int32 sds_id, VOIDP fill_value)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

fill_value OUT: Buffer for the returned fill value

Purpose Reads the fill value of a data set, if the value has been set.

Return value Returns SUCCEED (or 0) if a fill value is retrieved and FAIL (or -1) otherwise,

including when the fill value is not set.

Description SDgetfillvalue reads the fill value which has been set for the data set specified

by the parameter sds_id. It is assumed that the data type of the fill value is the

same as that of the data set.

Note that there are two FORTRAN-77 versions of this routine: **sfgfill** and **sfgcfill**. The **sfgfill** routine reads numeric fill value data and **sfgcfill** reads

character fill value data.

FORTRAN integer function sfgfill(sds_id, fill_value)

integer sds_id

<valid numeric data type> fill_value

integer function sfgcfill(sds_id, fill_value)

integer sds_id

character*(*) fill_value

SDgetinfo/sfginfo

intn SDgetinfo(int32 sds_id, char *sds_name, int32 *rank, int32 dimsizes[], int32 *data_type, int32 *num_attrs)

sds_id IN: Data set identifier returned by **SDcreate** and **SDselect**

sds_name OUT: Name of the data set

rank OUT: Number of dimensions in the data set

dimsizes OUT: Array containing the size of each dimension in the data set

data_type OUT: Data type for the data stored in the data set

num_attrs OUT: Number of attributes for the data set

Purpose Retrieves the name, rank, dimension sizes, data type and number of attributes

for a data set.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description SDgetinfo retrieves the name, number of dimensions, sizes of dimensions, data type, and number of attributes of the data set identified by *sds_id*, and stores

them in the parameters sds_name, rank, dimsizes, data_type, and num_attrs, respectively.

respectively.

The buffer sds_name can have at most 64 characters. If the name of the data set is not desired, then the parameter sds_name can be set to NULL in C and an

empty string in Fortran.

The maximum value of the *rank* parameter is MAX_VAR_DIMS (or 32).

If the data set is created with an unlimited dimension, then in the C interface, the first element of the *dimsizes* array (corresponding to the slowest-changing dimension) contains the number of records in the unlimited dimension; in the FORTRAN-77 interface, the last element of the *dimsizes* array (corresponding to the slowest-changing dimension) contains this information. Use **SDisrecord**

to determine if the data set has an unlimited dimension.

FORTRAN integer function sfginfo(sds_id, sds_name, rank, dimsizes, data_type, num_attrs)

character*(*) sds_name

integer sds_id, rank, dimsizes(*)

integer data_type, num_attrs

SDgetrange/sfgrange

intn SDgetrange(int32 sds_id, VOIDP max, VOIDP min)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

max OUT: Maximum value of the range

min OUT: Minimum value of the range

Purpose Retrieves the maximum and minimum values of the range.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description SDgetrange retrieves the maximum value of the range into the parameter max

and the minimum value into the parameter min. The maximum and minimum

values must be previously set via a call to **SDsetrange**.

It is assumed that the data type for the maximum and minimum range values

are the same as that of the data.

FORTRAN integer function sfgrange(sds_id, max, min)

integer sds_id

<valid numeric data type> max, min

SDidtoref/sfid2ref

int32 SDidtoref(int32 sds_id)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

Purpose Returns the reference number assigned to a data set.

Return value Returns the data set reference number if successful and FAIL (or -1) otherwise.

Description SDidtoref returns the reference number of the data set specified by the parameter *sds_id*. The reference number is assigned by the HDF library when

the data set is created. The specified reference number can be used to add the data set to a vgroup as well as a means of using the HDF annotations interface

to annotate the data set.

FORTRAN integer function sfid2ref(sds_id)

integer sds_id

SDiscoordvar/sfiscvar

intn SDiscoordvar(int32 sds_id)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

Purpose Determines if a data set is a coordinate variable.

Return value Returns TRUE (or 1) if the data set is a coordinate variable, and FALSE (or 0)

otherwise.

Description SDiscoordvar determines if the data set specified by the parameter sds_id is a

coordinate variable.

Coordinate variables are created to store metadata associated with dimensions.

To ensure compatibility with netCDF, coordinate variables are implemented as

data sets.

FORTRAN integer function sfiscvar(sds_id)

integer sds_id

SDisdimval_bwcomp/sfisdmvc

intn SDisdimval_bwcomp(int32 dim_id)

dim_id IN: Dimension identifier returned by **SDgetdimid**

Purpose Determines whether a dimension has the old and new representations or the

new representation only.

Refer to the HDF User's Guide, Chapter 3, titled SD Scientific Data Sets (SD

API), for information on old and new dimension representations.

Return value Returns SD_DIMVAL_BW_COMP (or 1) if backward compatible,

SD_DIMVAL_BW_INCOMP (or 0) if incompatible, FAIL (or -1) if error.

Description SDisdimval_bwcomp will flag the dimension specified by the parameter

dim_id as backward-compatible if a vdata with a class name of "DimVal0.0" does not exist in the vgroup for that dimension. If the vdata does exist, the specified dimension will be identified by **SDisdimval_bcomp** as backward-

incompatible.

The compatibility mode can be changed by calls to **SDsetdimval_comp** at any

time between the calls to **SDstart** and **SDend**.

FORTRAN integer function sfisdmvc(dim_id)

integer dim_id

SDisrecord/sfisrcrd

int32 SDisrecord(int32 sds_id)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

Purpose Determines whether a data set is appendable.

Return value Returns TRUE (or 1) if the data set is appendable, and FALSE (or 0) otherwise.

Description SDisrecord will determine if the data set specified by the parameter sds_id is

appendable, which means that the slowest-changing dimension was declared

unlimited when the data set was created.

FORTRAN integer sfisrcrd(sd_id)

integer sd id

SDnametoindex/sfn2index

int32 SDnametoindex(int32 sd_id, char *sds_name)

sd_id IN: SD interface identifier returned by SDstart

sds_name IN: Name of the data set

Purpose Determines the index of a data set given its name.

Return value Returns the index of the data set (sds_index) if the data set is found and FAIL

(or -1) otherwise.

Description SDnametoindex returns the index of the data set with the name specified by

the parameter *sds_name*. The routine does not accept wildcards in the specified data set name. It also searches on that name in a case-sensitive manner. If there are more than one data set with the same name, the routine will return the index

of the first one.

FORTRAN integer function sfn2index(sd_id, sds_name)

integer sd_id

character*(*) sds_name

SDreadattr/sfrnatt/sfrcatt

intn SDreadattr(int32 obj_id, int32 attr_index, VOIDP attr_buf)

obj_id IN: Identifier of the object the attribute is attached to

attr_index IN: Index of the attribute to be read

attr buf OUT: Buffer for the attribute values

Purpose Reads the values of an attribute.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description SDreadattr reads the values of the attribute specified by the parameter

attr_index and stores the values in the buffer attr_buf. It is assumed that the user has called **SDattrinfo** to retrieve the number of attribute values and allocate sufficient space for the buffer. Note that the routine does not read a

subset of attribute values.

The value of obj_id can be either an SD interface identifier (sd_id) , returned by **SDstart**, a data set identifier (sds_id) , returned by **SDselect**, or a dimension

identifier (dim_id), returned by SDgetdimid.

The value of *attr_index* is a positive integer and is less than the total number of attributes. The index value can be obtained using the routines **SDnametoindex** and **SDreftoindex**. The total number of attributes for the object can be obtained using the routines **SDgetinfo**, **SDattrinfo**, **SDdiminfo** and **SDfileinfo**.

Note that this routine has two FORTRAN-77 versions: **sfrnatt** and **sfrcatt**. The **sfrnatt** routine reads numeric attribute data and **sfrcatt** reads character attribute data.

```
FORTRAN integer function sfrnatt(obj_id, attr_index, attr_buffer)

SDreadchunk/sfrchnk/sfrcchnk

intn SDreadchunk(int32 sds_id, int32 *origin, VOIDP datap)

OUT:

IN: Data set identifier returned by **SDcreate** or **SDselect** sds_id

Origin of the chunk to be read origin IN:

datap Buffer for the chunk to be read

Purpose Reads a data chunk from a chunked data set.

Returns Succeed (or 0) if successful and FAIL (or -1) otherwise. **Return value**

Description

SDreadchunk reads the entire chunk of data from the chunked data set identified by the parameter sds_id, and stores the data in the buffer datap. Reading starts at the location specified by the parameter origin. SDreadchunk is used when an entire chunk of data is to be read. SDreaddata is used when the read operation is to be done regardless of the chunking scheme used in the data set.

The parameter *origin* specifies the coordinates of the chunk according to the chunk position in the chunked array. Refer to the Chapter 3 of the HDF User's Guide, titled Scientific Data Sets (SD API), for a description of the organization of chunks in a data set.

SDreadchunk will return FAIL (or -1) when an attempt is made to read from a non-chunked data set.

Note that there are two FORTRAN-77 versions of this routine; one for numeric data (sfrchnk) and one for character data (sfrcchnk).

```
FORTRAN
               integer sfrchnk(sds_id, origin, datap)
```

```
integer sds_id, origin(*)
```

<valid numeric data type> datap(*)

integer sfrcchnk(sds_id, origin, datap)

integer sds_id, origin(*)

character*(*) datap(*)

SDreaddata/sfrdata/sfrcdata

intn SDreaddata(int32 sds_id, int32 start[], int32 stride[], int32 edge[], VOIDP buffer)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

start IN: Array specifying the starting location from where data is read

stride IN: Array specifying the interval between the values that will be read

along each dimension

edge IN: Array specifying the number of values to be read along each

dimension

buffer OUT: Buffer to store the data read

Purpose Reads a subsample of data from a data set or coordinate variable.

Return value Returns SUCCEED (or 0) if successful or if the data set or coordinate variable

contains no data and FAIL (or -1) otherwise.

Description SDreaddata reads the specified subsample of data from the data set or coordinate variable identified by the parameter *sds_id*. The read data is stored in the buffer *buffer*. The subsample is defined by the parameters *start*, *stride*

and edge.

The array *start* specifies the starting position from where the subsample will be read. Valid values of each element in the array *start* are from 0 to the size of the corresponding dimension of the data set - 1. The dimension sizes are returned by **SDgetinfo**.

The array edge specifies the number of values to read along each data set dimension.

The array *stride* specifies the reading pattern along each dimension. For example, if one of the elements of the array *stride* is 1, then every element along the corresponding dimension of the data set will be read. If one of the elements of the array *stride* is 2, then every other element along the corresponding dimension of the data set will be read, and so on. Specifying *stride* value of NULL in the C interface or setting all values of the array *stride* to 1 in either interface specifies the contiguous reading of data. If all values in the array *stride* are set to 0, **SDreaddata** returns FAIL (or -1). No matter what stride value is provided, data is always placed contiguously in the buffer.

When reading data from a "chunked" data set using **SDreaddata**, consideration should be given to the issues presented in the section on chunking in Chapter 3 of the HDF User's Manual, titled *Scientific Data Sets* (SD API) and Chapter 13 of the HDF User's Manual, titled HDF Performance Issues.

Note that there are two FORTRAN-77 versions of this routine; **sfrdata** and **sfrcdata**. The **sfrdata** routine reads numeric scientific data and **sfrcdata** reads character scientific data.

Note

Regarding an important difference between the SD and GR interfaces:

The SD and GR interfaces differ in the correspondence between the dimension order in parameter arrays such as *start*, *stride*, *edge*, and *dimsizes* and the dimension order in the *data* array. See the **SDreaddata** and **GRreadimage** reference manual pages for discussions of the SD and GR approaches, respectively.

When writing applications or tools to manipulate both images and twodimensional SDs, this crucial difference between the interfaces must be taken into account. While the underlying data is stored in row-major order in both cases, the API parameters are not expressed in the same way. Consider the example of an SD data set and GR image that are stored as identically-shaped arrays of X columns by Y rows and accessed via the **SDreaddata** and **GRreadimage** functions, respectively. Both functions take the parameters start, stride, and edge.

- For **SDreaddata**, those parameters are expressed in (y,x) or [row,column] order. For example, start[0] is the starting point in the Y dimension and start[1] is the starting point in the X dimension. The same ordering holds true for all SD data set manipulation functions.
- For **GRreadimage**, those parameters are expressed in (x,y) or [column,row] order. For example, start[0] is the starting point in the X dimension and start[1] is the starting point in the Y dimension. The same ordering holds true for all GR functions manipulating image data.

```
FORTRAN
```

```

integer sds_id, start(*), stride(*), edge(*)
character*(*) buffer
```

SDreftoindex/sfref2index

int32 SDreftoindex(int32 sd_id, int32 sds_ref)

sd_id IN: SD interface identifier returned by SDstart

sds_ref IN: Reference number of the data set

Purpose Returns the index of a data set given the reference number.

Return value Returns the index of the data set (sds_index) if the data set is found and FAIL

(or -1) otherwise.

Description SDreftoindex returns the index of a data set identified by its reference number,

sds_ref.

The value of sds_index returned by SDreftoindex can be passed to SDselect to

obtain a data set identifier (sds_id).

FORTRAN integer function sfref2index(sd_id, sds_ref)

integer sd_id, sds_ref

SDselect/sfselect

int32 SDselect(int32 sd_id, int32 sds_index)

sd_id IN: SD interface identifier returned by SDstart

sds_index IN: Index of the data set

Purpose Obtains the data set identifier (*sds_id*) of a data set.

Return value Returns the data set identifier (sds_id) if successful and FAIL (or -1)

otherwise.

Description SDselect obtains the data set identifier (sds_id) of the data set specified by its

index, sds_index.

The integration with netCDF has required that a dimension (or coordinate variable) is stored as a data set in the file. Therefore, the value of *sds_index* may correspond to the coordinate variable instead of the actual data set. Users should use the routine **SDiscoordvar** to determine whether the given data set is

a coordinate variable.

The value of *sds_index* is greater than or equal to 0 and less than the number of data sets in the file. The total number of data sets in a file may be obtained from a call to **SDfileinfo**. The **SDnametoindex** routine can be used to find the

index of a data set if its name is known.

FORTRAN integer function sfselect(sd id, sds index)

integer sd_id, sds_index

SDsetattr/sfsnatt/sfscatt

intn SDsetattr(int32 obj_id, char *attr_name, int32 data_type, int32 count, VOIDP values)

obj id IN: Identifier of the object the attribute is to be attached to

attr_name IN: Name of the attribute

data_type IN: Data type of the values in the attribute

count IN: Total number of values to be stored in the attribute

values IN: Data values to be stored in the attribute

Purpose Attaches an attribute to an object.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description

SDsetattr attaches the attribute to the object specified by the *obj_id* parameter. The attribute is defined by its name, *attr_name*, data type, *data_type*, number of attribute values, *count*, and the attribute values, *values*. **SDsetattr** provides a generic way for users to define metadata. It implements the label = value data abstraction.

The value of *obj_id* can be an SD interface identifier (*sd_id*), returned by **SDcreate**, a data set identifier (*sds_id*), returned by **SDselect**, or a dimension identifier (*dim_id*), returned by **SDgetdimid**.

If an SD interface identifier (sd_id) is specified as the obj_id parameter, a global attribute is created which applies to all objects in the file. If a data set identifier (sds_id) is specified as the obj_id parameter, an attribute is attached to the specified data set. If a dimension identifier (dim_id) is specified as the obj_id parameter, an attribute is attached to the specified dimension.

The attr_name argument can be any ASCII string.

The *data_type* parameter can contain any data type supported by the HDF library. These data types are listed in Table 1A in Section I of this manual.

Attribute values are passed in the parameter *values*. The number of attribute values is defined by the *count* parameter. If more than one value is stored, all values must have the same data type. If an attribute with the given name, data type and number of values exists, it will be overwritten.

Note that there are two FORTRAN-77 versions of this routine; **sfsnatt** and **sfscatt**. The **sfsnatt** routine writes numeric attribute data and **sfscatt** writes character attribute data.

FORTRAN

```
integer obj_id, data_type, count
```

character*(*) attr_name

SDsetblocksize/sfsblsz

intn SDsetblocksize(int32 sd_id, int32 block_size)

sd_id IN: SD interface identifier returned by SDstart

block_size IN: Size of the block in bytes

Purpose Sets the block size used for storing data sets with unlimited dimensions.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description SDsetblocksize sets the block size defined in the parameter block_size for all

data sets in the file. SDsetblocksize is used when creating new data sets only;

it has no effect on pre-existing data sets.

SDsetblocksize must be used after calls to SDcreate or SDselect and before

the call to SDwritedata.

The *block_size* parameter should be set to a multiple of the desired buffer size.

FORTRAN integer sfsblsz(sd_id, block_size)

integer sd_id, block_size

SDsetcal/sfscal

intn SDsetcal(int32 sds_id, float64 cal, float64 cal_err, float64 offset, float64 offset_err, int32 data_type)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

cal IN: Calibration factor

cal_err IN: Calibration error

offset IN: Uncalibrated offset

offset_err IN: Uncalibrated offset error

data_type IN: Data type of uncalibrated data

Purpose Sets the calibration information.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description SDsetcal stores the calibration record associated with a data set. A calibration record contains the following information:

cal	Calibration factor
cal_err	Calibration error
offset	Uncalibrated offset
offset_err	Uncalibrated offset error
data_type	Data type of uncalibrated data

The relationship between a value cal_value stored in a data set and the original value is defined as: orig_value = cal * (cal_value - offset).

The variable offset_err contains a potential error of offset, and cal_err contains a potential error of cal. Currently the calibration record is provided for information only. The SD interface performs no operations on the data based on the calibration tag.

The calibration information is automatically cleared after a call to **SDreaddata** or **SDwritedata**. Therefore, **SDsetcal** must be called once for each data set that is to be read or written.

 $\begin{tabular}{ll} FORTRAN & integer function sfscal(sds_id, cal, cal_err, offset, offset_err, \\ & data_type) \end{tabular}$

integer sds_id, data_type
real*8 cal, cal_err, offset, offset_err

SDsetchunk/sfschnk

intn SDsetchunk(int32 sds_id, HDF_CHUNK_DEF cdef, int32 flag)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

C only:

cdef IN: Pointer to the chunk definition

flag IN: Compression flag

Fortran only:

dim_length IN: Chunk dimensions array

comp_type IN: Type of compression

comp_prm IN: Compression parameters array

Purpose Sets the chunk size and the compression method, if any, of a data set.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description SDsetchunk makes the data set specified by the parameter sds_id a chunked data set according to the chunking and compression information provided in

the parameters *cdef* and *flag* in C, and in the parameters *comp_type* and

comp_prm in Fortran.

C only:

The parameter *flag* specifies the type of the data set, i.e., if the data set is chunked or chunked and compressed with either RLE, Skipping Huffman, GZIP, Szip, or NBIT compression methods. Valid values of *flag* are HDF_CHUNK for a chunked data set, HDF_CHUNK | HDF_COMP for a chunked data set compressed with RLE, Skipping Huffman, Szip, or GZIP compression methods, and HDF_CHUNK | HDF_NBIT for a chunked NBIT-compressed data set.

Chunking and compression information is passed in the parameter *cdef*. The parameter *cdef* has a type of HDF_CHUNK_DEF, defined in the HDF library as follows:

There are three pieces of chunking and compression information which should be specified: chunking dimensions, compression type, and, if needed, compression parameters.

If the data set is chunked, i.e., flag value is HDF_CHUNK, then chunk_lengths[] elements of cdef union (cdef.chunk_lengths[]) have to be initialized to the chunk dimensions.

If the data set is chunked and compressed using RLE, Skipping Huffman or GZIP methods (i.e., flag value is set up to HDF_CHUNK | HDF_COMP), then the elements chunk_lengths[] of the structure comp in the union cdef (cdef.comp.chunk_lengths[]) have to be initialized to the chunk dimensions.

If the data set is chunked and NBIT compression is applied (i.e., flag values is set up to hdf_chunk | hdf_nbit), then the elements chunk_lengths[] of the structure nbit in the union cdef (cdef.nbit.chunk_lengths[]) have to be initialized to the chunk dimensions.

Compression types are passed in the field <code>comp_type</code> of the structure <code>cinfo</code>, which is an element of the structure <code>comp</code> in the union <code>cdef(cdef.comp.cinfo.comp_type)</code>. Valid compression types are: <code>comp_code_Rlef(comp.code_skphuff)</code> for Skipping Huffman, <code>comp_code_szip</code> for Szip compression, and <code>comp_code_deflate</code> for GZIP compression.

For Skipping Huffman and GZIP compression parameters are passed in corresponding fields of the structure cinfo. Specify skipping size for Skipping Huffman compression in the field cdef.comp.cinfo.skphuff.skp_size; this value must be 1 or greater. Specify the deflate level for GZIP compression in the field cdef.comp.cinfo.deflate_level. Valid deflate level values are integers between 0 and 9 inclusive.

For Szip compression, parameters must be passed in a structure identical to the structure described in the **SDsetcompress** reference manual entry.

Refer to the **SDsetcompress** page in this manual for the definition of the structure comp_info.

NBIT compression parameters are specified in the fields start_bit, bit_len, sign_ext, and fill_one in the structure nbit of the union *cdef*.

Fortran only:

The *dim_length* array specifies the chunk dimensions.

The *comp_type* parameter specifies the compression type. Valid compression types and their values are defined in the hdf.inc file, and are listed below.

- COMP CODE NONE (or 0) for uncompressed data
- COMP_CODE_RLE (or 1) for data compressed using the RLE compression algorithm
- COMP_CODE_NBIT (or 2) for data compressed using the NBIT compression algorithm
- COMP_CODE_SKPHUFF (or 3) for data compressed using the Skipping Huffman compression algorithm
- COMP_CODE_DEFLATE (or 4) for data compressed using the GZIP compression algorithm
- COMP_CODE_SZIP (or 5) for data compressed using the Szip compression algorithm

The *comp_prm*(1) parameter specifies the skipping size for the Skipping Huffman compression method and the deflate level for the GZIP compression method. The skipping size value must be 1 or greater; the deflate level must be an integer value between 0 and 9 inclusive.

For NBIT compression, the four elements of the array <code>comp_prm</code> correspond to the four NBIT compression parameters listed in the structure <code>nbit</code>. The value of <code>comp_prm(1)</code> should be set to the value of <code>start_bit</code>, the value of <code>comp_prm(2)</code> should be set to the value of <code>bit_len</code>, the value of <code>comp_prm(3)</code> should be set to the value of <code>sign_ext</code>, and the value of <code>comp_prm(4)</code> should be set to the value of <code>fill_one</code>. See the <code>hdf_chunk_def</code> union description and the description of <code>SDsetnbitdataset</code> function for NBIT compression parameters definitions.

```
FORTRAN
```

```
integer sfschnk(sds_id, dim_length, comp_type, comp_prm)
```

integer sds_id, dim_length, comp_type, comp_prm(*)

SDsetchunkcache/sfscchnk

intn SDsetchunkcache(int32 sds_id, int32 maxcache, int32 flag)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

maxcache IN: Maximum number of chunks in the cache

flag IN: Flag determining the behavior of the routine

Purpose Sets the size of the chunk cache.

Return value Returns the maximum number of chunks that can be cached (the value of the

parameter maxcache) if successful and FAIL (or -1) otherwise.

Description SDsetchunkcache sets the size of the chunk cache to the value of the

parameter maxcache.

Currently the only allowed value of the parameter flag is 0, which designates

default operation.

By default, when a generic data set is promoted to be a chunked data set, the parameter *maxcache* is set to the number of chunks along the fastest changing

dimension and a cache for the chunks is created.

If the chunk cache is full and the value of the parameter *maxcache* is greater then the current *maxcache* value, then the chunk cache is reset to the new value of *maxcache*. Otherwise the chunk cache remains at the current value of *maxcache*. If the chunk cache is not full, then the chunk cache is set to the new value of *maxcache* only if the new *maxcache* value is greater than the current number of chunks in the cache.

Do not set the value of *maxcache* to be less than the number of chunks along the fastest-changing dimension of the biggest slab to be written or read via **SDreaddata** or **SDwritedata**. Doing this will cause internal thrashing. See the section on chunking in Chapter 13, "HDF Performance Issues," in the *HDF User's Guide*, for more information on this.

FORTRAN integer sfscchnk(sds_id, maxcache, flag)

integer sds_id, maxcache, flag

SDsetcompress/sfscompress

intn SDsetcompress(int32 sds_id, int32 comp_type, comp_info *c_info)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

comp_type IN: Compression method

C only:

c_info IN: Pointer to the comp_info union

Fortran only:

comp_prm IN: Compression parameters array

Purpose Compresses the data set with the specified compression method.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description

SDsetcompress compresses the data set identified by the parameter sds_id according to the compression method specified by the parameter $comp_type$ and the compression information specified by the parameter c_info in C and $comp_prm$ in Fortran. **SDsetcompress** compresses the data set data at the time it is called, not during the next call to **SDwritedata**.

SDsetcompress is a simplified interface to the **HCcreate** routine and should be used instead of **HCcreate** unless the user is familiar with working with the lower-level routines.

The parameter *comp_type* is the compression type definition and is set to COMP_CODE_RLE (or 1) for run-length encoding (RLE), COMP_CODE_SKPHUFF (or 3) for Skipping Huffman, COMP_CODE_DEFLATE (or 4) for GZIP compression, COMP_CODE_SZIP (or 5) for Szip compression, or COMP_CODE_NONE (or 0) for no compression.

The parameter c_info is a pointer to a union structure of type comp_info. This union structure is defined as follows:

```
typedef union tag_comp info
   struct
   /* Not used by SDsetcompress */
   struct
   /* Not used by SDsetcompress */
   } nbit;
    { /* struct to contain info about how to compress size of the
       elements when skipping */
       intn skp size;
   } skphuff;
   struct
    { /* struct to contain info about how to compress or decompress
       gzip encoded dataset how hard to work when compressing
       data*/
       intn level;
   } deflate;
   struct
    { /* struct to contain info about how to compress or decompress
       szip encoded dataset*/
       int32 bits_per_pixel;
       int32 compression mode;
       int32 options_mask;
       int32 pixels;
       int32 pixels per block;
       int32 pixels_per_scanline;
   } szip;
} comp info;
```

The skipping size for the Skipping Huffman algorithm must be 1 or greater and is specified in the field c_info.skphuff.skp_size in C and in the parameter $comp_prm(1)$ in Fortran.

The deflate level for the GZIP algorithm is specified in the c_info.deflate.level field in C and in the parameter $comp_prm(1)$ in Fortran. Valid values are integers between 0 and 9 inclusive.

```
FORTRAN integer sfscompress(sds_id, comp_type, comp_prm)

integer sds_id, comp_type, comp_prm(*)
```

SDsetdatastrs/sfsdtstr

intn SDsetdatastrs(int32 sds_id, char *label, char *unit, char *format, char *coordsys)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

label IN: Label (predefined attribute)

unit IN: Unit (predefined attribute)

format IN: Format (predefined attribute)

coordsys IN: Coordinate system (predefined attribute)

Purpose Sets the predefined attributes for a data set.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description SDsetdatastrs sets the predefined attributes of the data set, identified by

sds_id, to the values specified in the parameters label, unit, format and coordsys. The predefined attributes are label, unit, format, and coordinate system. If the user does not want a string returned, the corresponding

parameter can be set to NULL in C and an empty string in Fortran.

For more information about predefined attributes, refer to Section 3.10 of the

HDF User's Guide.

FORTRAN integer function sfsdtstr(sds_id, label, unit, format, coordsys)

integer sds_id

character*(*) label, unit, format, coordsys

SDsetdimname/sfsdmname

intn SDsetdimname(int32 dim_id, char *dim_name)

dim_id IN: Dimension identifier returned by **SDgetdimid**

dim_name IN: Name of the dimension

Purpose Assigns a name to a dimension.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description SDsetdimname sets the name of the dimension identified by the parameter

dim_id to the value specified in the parameter dim_name. Dimensions that are not explicitly named by the user will have the default name of "fakeDim[x]"

specified by the HDF library, where [x] denotes the dimension index.

If another dimension exists with the same name it is assumed that they refer to the same dimension object and changes to one will be reflected in the other. If the dimension with the same name has a different size, an error condition will

result.

Naming dimensions is optional but encouraged.

The length of the parameter *dim_name* can be at most 64 characters.

FORTRAN integer function sfsdmname(dim_id, dim_name)

integer dim_id

character*(*) dim_name

SDsetdimscale/sfsdscale

intn SDsetdimscale(int32 dim_id, int32 count, int32 data_type, VOIDP data)

dim_idIN:Dimension identifier returned by SDgetdimidcountIN:Total number of values along the dimensiondata_typeIN:Data type of the values along the dimensiondataIN:Value of each increment along the dimension

Purpose Stores the values of a dimension.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description SDsetdimscale stores scale information for the dimension identified by the parameter *dim_id*. Note that it is possible to store dimension scale values

without naming the dimension.

For fixed-size arrays, the value of count must be equal to the dimension

size or the routine will fail.

Note that, due to the existence of the parameter data_type, the dimension

scales need not have the same data type as the data set.

Note that if **SDsetdimscale** is called and **SDsetdimname** is subsequently called for the same dimension, **SDsetdimscale** must be called again to

reassociate the scale with the new name.

FORTRAN integer function sfsdscale(dim_id, count, data_type, data)

integer dim_id, count, data_type

<valid data type> data(*)

SDsetdimstrs/sfsdmstr

intn SDsetdimstrs(int32 dim_id, char *label, char *unit, char *format)

dim_id IN: Dimension identifier returned by **SDgetdimid**

label IN: Label (predefined attribute)

unit IN: Unit (predefined attribute)

format IN: Format (predefined attribute)

Purpose Sets the predefined attribute of a dimension.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description SDsetdimstrs sets the predefined attribute (label, unit, and format) for a

dimension and its scale to the values specified in the parameters *label*, *unit* and *format*. If a parameter is set to NULL in C and an empty string in Fortran, then the attribute corresponding to that parameter will not be written. For more information about predefined attributes, refer to Section 3.10 of the HDF

User's Guide.

FORTRAN integer function sfsdmstr(dim_id, label, unit, format)

integer dim_id

character*(*) label, unit, format

SDsetdimval_comp/sfsdmvc

intn SDsetdimval_comp(int32 dim_id, intn comp_mode)

dim_id IN: Dimension identifier returned by **SDgetdimid**

comp_mode IN: Compatibility mode to be set

Purpose Determines whether a dimension *will have* the old and new representations or

the new representation only.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description SDsetdimval_comp sets the compatibility mode specified by the comp_mode

parameter for the dimension identified by the *dim_id* parameter. The two possible compatibility modes are: "backward-compatible" mode, which implies that the old and new dimension representations are written to the file, and "backward-incompatible" mode, which implies that only the new

dimension representation is written to the file.

Unlimited dimensions are always backward-compatible, therefore

SDsetdimval_comp takes no action on unlimited dimensions.

As of HDF version 4.1r1, the default mode is backward-incompatible. Subsequent calls to **SDsetdimval_comp** will override the settings established

in previous calls to the routine.

The comp_mode parameter can be set to SD_DIMVAL_BW_COMP (or 1), which specifies backward-compatible mode, or SD_DIMVAL_BW_INCOMP (or 0), which

specifies backward-incompatible mode.

FORTRAN integer function sfsdmvc(dim_id, comp_mode)

integer dim id, comp mode

SDsetexternalfile/sfsextf

intn SDsetexternalfile(int32 sds_id, char *filename, int32 offset)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

filename IN: Name of the external file

offset IN: Number of bytes from the beginning of the external file to where the

data will be written

Purpose Stores data in an external file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description SDsetexternalfile allows users to move the actual data values (i.e., not metadata) of a data set, sds_id , into the external data file named by the

parameter *filename*, and started at the offset specified by the parameter *offset*. The metadata remains in the original file. Note that this routine works only

with HDF post-version 3.2 files.

Data can only be moved once for any given data set, and it is the user's responsibility to make sure the external data file is kept with the "original" file.

If the data set already exists, its data will be moved to the external file. Space occupied by the data in the primary file will not be released. To release the space in the primary file use the hdfpack command-line utility. If the data set does not exist, its data will be written to the external file during the consequent calls to **SDwritedata**.

See the Reference Manual entries for **HXsetcreatedir** and **HXsetdir** for more information on the options available for accessing external files.

FORTRAN integer function sfsextf(sds_id, file_name, offset)

integer sds_id, offset
character*(*) file_name

SDsetfillmode/sfsflmd

intn SDsetfillmode(int32 *sd_id*, intn *fill_mode*)

sd id IN: SD interface identifier returned by SDstart

fill_mode IN: Fill mode

Purpose Sets the current fill mode of a file.

Return value Returns the fill mode value before it was reset if successful and FAIL (or -1)

otherwise.

Description SDsetfillmode applies the fill mode specified by the parameter *fill_mode* to all

data sets contained in the file identified by the parameter *sd_id*.

Possible values of *fill_mode* are SD_FILL (or 0) and SD_NOFILL (or 256). SD_FILL is the default mode, and indicates that fill values will be written when the data set is created. SD_NOFILL indicates that fill values will not be written.

When a data set without unlimited dimensions is created, by default the first **SDwritedata** call will fill the entire data set with the default or user-defined fill value (set by **SDsetfillvalue**). In data sets with an unlimited dimension, if a new write operation takes place along the unlimited dimension beyond the last location of the previous write operation, the array locations between these written areas will be initialized to the user-defined fill value, or the default fill value if a user-defined fill value has not been specified.

If it is certain that all data set values will be written before any read operation takes place, there is no need to write the fill values. Simply call **SDsetfillmode** with *fill_mode* value set to SD_NOFILL, which will eliminate all fill value write operations to the data set. For large data sets, this can improve the speed by almost 50%.

FORTRAN integer function sfsflmd(sd_id, fill_mode)

integer sd_id, fill_mode

SDsetfillvalue/sfsfill/sfscfill

intn SDsetfillvalue(int32 sds_id, VOIDP fill_value)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

fill_value IN: Fill value

Purpose Sets the fill value for a data set.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description SDsetfillvalue sets the fill value specified by the fill_value parameter for the

data set identified by the *sds_id* parameter.

The fill value is assumed to have the same data type as the data set.

It is recommended to call **SDsetfillvalue** before writing data.

FORTRAN integer function sfsfill(sds_id, fill_value)

integer sds_id

integer sds_id

character*(*) fill_value

SDsetnbitdataset/sfsnbit

intn SDsetnbitdataset(int32 sds_id, intn start_bit, intn bit_len, intn sign_ext, intn fill_one)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

start_bit IN: Leftmost bit of the field to be written

bit len IN: Length of the bit field to be written

sign_ext IN: Sign extend specifier

fill_one IN: Background bit specifier

Purpose Specifies a non-standard bit length for the data set values.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description

SDsetnbitdataset allows the HDF user to specify that the data set identified by the parameter sds_id contains data of a non-standard length defined by the parameters $start_bit$ and bit_len . Additional information about the non-standard bit length decoding are specified in the parameters $sign_ext$ and $fill_one$.

Any length between 1 and 32 bits can be specified. After **SDsetnbitdataset** has been called for the data set array, any read or write operations will involve a conversion between the new data length of the data set array and the data length of the read or write buffer.

Bit lengths of all data types are counted from the right of the bit field starting with 0. In a bit field containing the values 01111011, bits 2 and 7 are set to 0 and all the other bits are set to 1.

The *start_bit* parameter specifies the leftmost position of the variable-length bit field to be written. For example, in the bit field described in the preceding paragraph a *start_bit* parameter set to 4 would correspond to the fourth bit value of 1 from the right.

The *bit_len* parameter specifies the number of bits of the variable-length bit field to be written. This number includes the starting bit and the count proceeds toward the right end of the bit field - toward the lower-bit numbers. For example, starting at bit 5 and writing 4 bits of the bit field described in the preceding paragraph would result in the bit field 1110 being written to the data set. This would correspond to a *start_bit* value of 5 and a *bit_len* value of 4.

The <code>sign_ext</code> parameter specifies whether to use the leftmost bit of the variable-length bit field to sign-extend to the leftmost bit of the data set data. For example, if 9-bit signed integer data is extracted from bits 17-25 and the bit in position 25 is 1, then when the data is read back from disk, bits 26-31 will be set to 1. Otherwise bit 25 will be 0 and bits 26-31 will be set to 0. The <code>sign_ext</code> parameter can be set to <code>TRUE</code> (or 1) or <code>FALSE</code> (or 0) - specify <code>TRUE</code> to sign-extend.

The *fill_one* specifies whether to fill the "background" bits with the value 1 or 0. This parameter can also be set to TRUE or FALSE.

The "background" bits of a variable-length data set are the bits that fall outside of the variable-length bit field stored on disk. For example, if five bits of an unsigned 16-bit integer data set located in bits 5 to 9 are written to disk with the *fill_one* parameter set to TRUE (or 1), then when the data is reread into memory bits 0 to 4 and 10 to 15 would be set to 1. If the same 5-bit data was written with a *fill_one* value of FALSE (or 0), then bits 0 to 4 and 10 to 15 would be set to 0.

This bit operation is performed before the sign-extend bit-filling. For example, using the *sign_ext* example above, bits 0 to 16 and 26 to 31 will first be set to the "background" bit value, and then bits 26 to 31 will be set to 1 or 0 based on the value of the 25th bit.

FORTRAN

integer sds_id, start_bit, bit_len, sign_ext, fill_one

SDsetrange/sfsrange

intn SDsetrange(int32 sds_id, VOIDP max, VOIDP min)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

max IN: Maximum value of the range

min IN: Minimum value of the range

Purpose Sets the maximum and minimum range values for a data set.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description SDsetrange sets the maximum and minimum range values of the data set

identified by the parameter sds_id with the values of the parameters max and min. The term "range" is used here to describe the range of numeric values

stored in a data set.

It is assumed that the data type for the maximum and minimum range values

are the same as the data type of the data.

This routine does not compute the maximum and minimum range values, it only stores the values as given. As a result, the maximum and minimum range values may not always reflect the actual maximum and minimum range values

in the data set data.

FORTRAN integer function sfsrange(sds_id, max, min)

integer sds_id

<valid numeric data type> max, min

SDstart/sfstart

int32 SDstart(char *filename, int32 access_mode)

filename IN: Name of the HDF file

access_mode IN: The file access mode in effect during the current session

Purpose Opens an HDF file and initializes an SD interface.

Return value Returns an SD interface identifier if successful and FAIL (or -1) otherwise.

Description SDstart opens the file with the name specified by the parameter *filename*, with the access mode specified by the parameter *access_mode*, and returns an SD

interface identifier (sd_id) . This routine must be called for each file before any other SD calls can be made on that file.

The type of identifier returned by **SDstart** is currently not the same as the identifier returned by **Hopen**. As a result, the SD interface identifiers (sd_id) returned by this routine are not understood by other HDF interfaces.

To mix SD API calls and other HDF API calls, use **SDstart** and **Hopen** on the same file. **SDstart** must precede all SD calls, and **Hopen** must precede all other HDF function calls. To terminate access to the file, use **SDend** to dispose of the SD interface identifier, sd_id , and **Hclose** to dispose of the file identifier, $file_id$.

The file identified by the parameter *filename* can be any one of the following: an XDR-based netCDF file, "old-style" DFSD file or a "new-style" SD file.

The value of the parameter *access_mode* can be one of the following:

DFACC_READ - Open existing file for read-only access. If the file does not exist, specifying this mode will cause **SDstart** to return fall (or -1).

DFACC_WRITE - Open existing file for read and write access. If the file does not exist, specifying this mode will cause **SDstart** to return fall (or -1).

DFACC_CREATE - Create a new file with read and write access. If the file has already existed, its contents will be replaced.

FORTRAN integer function sfstart(filename, access_mode)

character*(*) filename
integer access mode

SDwritechunk/sfwchnk/sfwcchnk

intn SDwritechunk(int32 sds_id, int32 *origin, VOIDP datap)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

origin IN: Origin of the chunk to be written

datap IN: Buffer for the chunk data to be written

Purpose Writes a data chunk to a chunked data set.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description SDwritechunk writes the entire chunk of data stored in the buffer *datap* to the

chunked data set identified by the parameter *sds_id*. Writing starts at the location specified by the parameter *origin*. **SDwritechunk** is used when an entire chunk of data is to be written. **SDwritedata** is used when the write operation is to be done regardless of the chunking scheme used in the data set.

SDwritechunk will return FAIL (or -1) when an attempt is made to use it to write to a non-chunked data set.

The parameter *origin* specifies the coordinates of the chunk according to the chunk position in the overall chunk array. Refer to Chapter 3 of the HDF User's Guide, titled *Scientific Data Sets (SD API)*, for a description of the organization of chunks in a data set.

Note that there are two FORTRAN-77 versions of this routine; one for numeric data (**sfwchnk**) and one for character data (**sfwchnk**).

```
FORTRAN integer sfwchnk(sds_id, origin, datap)
```

```
integer sds_id, origin
```

<valid numeric data type> datap(*)

integer sfwcchnk(sds_id, origin, datap)

integer sds_id, origin
character*(*) datap(*)

SDwritedata/sfwdata/sfwcdata

intn SDwritedata(int32 sds_id, int32 start[], int32 stride[], int32 edge[], VOIDP buffer)

sds_id IN: Data set identifier returned by **SDcreate** or **SDselect**

start IN: Array specifying the starting location of the data to be written

stride IN: Array specifying the number of values to skip along each dimension

edge IN: Array specifying the number of values to be written along each

dimension

buffer IN: Buffer for the values to be written

Purpose Writes a subsample of data to a data set or to a coordinate variable.

Return value Returns SUCCEED (or 0) if Successful and FAIL (or -1) otherwise.

Description

SDwritedata writes the specified subsample of data to the data set or coordinate variable identified by the parameter *sds_id*. The data is written from the buffer *buffer*. The subsample is defined by the parameters *start*, *stride* and *edge*.

The array *start* specifies the starting position from where the subsample will be written. Valid values of each element in the array *start* are from 0 to the size of the corresponding dimension of the data set - 1. The dimension sizes are returned by **SDgetinfo**.

The array edge specifies the number of values to write along each data set dimension.

The array *stride* specifies the writing pattern along each dimension. For example, if one of the elements of the array *stride* is 1, then every element along the corresponding dimension of the data set will be written. If one of the elements of the array *stride* is 2, then every other element along the corresponding dimension of the data set will be written, and so on. Specifying *stride* value of NULL in the C interface or setting all values of the array *stride* to 1 in either interface specifies the contiguous writing of data. If all values in the array *stride* are set to 0, **SDwritedata** returns FAIL (or -1).

When writing data to a chunked data set using **SDwritedata**, consideration should be given to be issues presented in the section on chunking in Chapter 3 of the HDF User's Manual, titled *Scientific Data Sets (SD API)* and Chapter 13 of the HDF User's Manual, titled *HDF Performance Issues*.

Note that there are two FORTRAN-77 versions of this routine; **sfwdata** and **sfwcdata**. The **sfwdata** routine writes numeric data and **sfwcdata** writes character scientific data.

Note

Regarding an important difference between the SD and GR interfaces:

The SD and GR interfaces differ in the correspondence between the dimension order in parameter arrays such as *start*, *stride*, *edge*, and *dimsizes* and the dimension order in the *data* array. See the **SDreaddata** and **GRreadimage** reference manual pages for discussions of the SD and GR approaches, respectively.

When writing applications or tools to manipulate both images and twodimensional SDs, this crucial difference between the interfaces must be taken into account. While the underlying data is stored in row-major order in both cases, the API parameters are not expressed in the same way. Consider the example of an SD data set and GR image that are stored as identically-shaped arrays of X columns by Y rows and accessed via the **SDreaddata** and **GRreadimage** functions, respectively. Both functions take the parameters start, stride, and edge.

- For **SDreaddata**, those parameters are expressed in (y,x) or [row,column] order. For example, start[0] is the starting point in the Y dimension and start[1] is the starting point in the X dimension. The same ordering holds true for all SD data set manipulation functions.
- For **GRreadimage**, those parameters are expressed in (x,y) or [column,row] order. For example, start[0] is the starting point in the X dimension and start[1] is the starting point in the Y dimension. The same ordering holds true for all GR functions manipulating image data

Vaddtagref/vfadtr

int32 Vaddtagref(int32 vgroup_id, int32 tag, int32 ref)

vgroup_id IN: Vgroup identifier returned by **Vattach**

tag IN: Tag of the object

ref IN: Reference number of the object

Purpose Inserts an object into a vgroup.

Return value Returns the number of objects in the vgroup if successful and FAIL (or -1)

otherwise.

Description Vaddtagref inserts the object identified by the parameters tag and ref into the

vgroup identified by the parameter *vgroup_id*.

If an object to be inserted is a data set, duplication of the tag/reference number pair will be allowed. Otherwise, the tag/reference number pair must be unique among the elements within the vgroup or the routine will return FAIL (or -1).

FORTRAN integer function vfadtr(vgroup_id, tag, ref)

integer vgroup_id, tag, ref

Vattach/vfatch

int32 Vattach(int32 file_id, int32 vgroup_ref, char *access)

file_id IN: File identifier returned by **Hopen**

vgroup_ref IN: Reference number for the vgroup

access IN: Type of access

Purpose Initiates access to a new or existing vgroup.

Return value Returns the vgroup identifier (vgroup_id) if successful and FAIL (or -1)

otherwise.

Description Vattach opens a vgroup with access type specified by the parameter *access* in the file identified by the parameter *file_id*. The vgroup is identified by the

reference number, vgroup_ref.

Vattach returns the vgroup identifier, *vgroup_id*, for the accessed vgroup. The *vgroup_id* is used for all subsequent operations on this vgroup. Once operations are complete, the vgroup identifier must be disposed of via a call to **Vdetach**. Multiple attaches may be made to the same vgroup simultaneously, and several vgroup identifiers can be created for the same vgroup. Each vgroup identifier must be disposed of independently.

The parameter *file_id* is the file identifier of an opened file. The parameter *vgroup_ref* specifies which vgroup in the file to attach to. If *vgroup_ref* is set to -1, a new vgroup will be created. If *vgroup_ref* is set to a positive number, the vgroup with that as a reference number is attached.

Possible values for the parameter access are "r" for read access and "w" for write access.

FORTRAN integer function vfatch(file_id, vgroup_ref, access)

integer file_id, vgroup_ref

character*1 access

Vattrinfo/vfainfo

intn Vattrinfo(int32 *vgroup_id*, intn *attr_index*, char **attr_name*, int32 **data_type*, int32 **count*, int32 **size*)

vgroup_id IN: Vgroup identifier returned by **Vattach**

attr_index IN: Index of the attribute

attr_name OUT: Name of the attribute

data_type OUT: Data type of the attribute

count OUT: Number of values in the attribute

size OUT: Size, in bytes, of the attribute values.

Purpose Retrieves the name, data type, number of values, and value size of an attribute

for a vgroup.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description Vattrinfo retrieves the name, datatype, number of values, and value size of an

attribute identified by its index, attr_index, in the vgroup, vgroup_id. Name, data type, number of values and size are retrieved into the parameters

attr_name, data_type, count, and size, respectively.

If the attribute's name, data type, number of values, or value size are not

needed, the corresponding output parameters can be set to NULL.

The valid value *attr_index* range from 0 to the total number of attributes attached to a vgroup - 1. The number of vgroup attributes can be obtained

using Vnattrs.

FORTRAN integer function vfainfo(vgroup_id, attr_index, attr_name, data_type, count, size)

integer vgroup_id, attr_index, data_type, count, size

character*(*) attr_name

Vdelete/vdelete

int32 Vdelete(int32 file_id, int32 vgroup_ref)

file_id IN: File identifier returned by **Hopen**

vgroup_ref IN: Vgroup reference number returned by Vattach

Purpose Remove a vgroup from a file.

Return value Returns Succeed (or 0) if successful and Fail (or -1) if not successful.

Description Vdelete removes the vgroup identified by the parameter vgroup_ref from the

file identified by the parameter file_id.

This routine will remove the vgroup from the internal data structures and from

the file.

FORTRAN integer function vdelete(file_id, vgroup_ref)

integer file_id, vgroup_ref

Vdeletetagref/vfdtr

int32 Vdeletetagref(int32 vgroup_id, int32 tag, int32 ref)

vgroup_id IN: Vgroup identifier returned by **Vattach**

tag IN: Tag of the object

ref IN: Reference number of the object

Purpose Deletes an object from a vgroup.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) if not successful or the

given tag/reference number pair is not found in the vgroup.

Description Vdeletetagref deletes the object specified by the parameters tag and ref from

the vgroup identified by the parameter *vgroup_id*. **Vinqtagref** should be used to check if the tag/reference number pair exists before calling this routine.

If duplicate tag/reference number pairs are found in the vgroup, **Vdeletetagref** deletes the first occurrence. **Vinqtagref** should be used to determine if

duplicate tag/reference number pairs exist in the vgroup.

FORTRAN integer function vfdtr(vgroup_id, tag, ref)

integer vgroup_id, tag, ref

Vdetach/vfdtch

int32 Vdetach(int32 vgroup_id)

vgroup_id IN: Vgroup identifier returned by **Vattach**

Purpose Terminates access to a vgroup.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description Vdetach detaches the currently-attached vgroup identified by vgroup_id and

terminates access to that vgroup.

All space associated with the vgroup, $vgroup_id$, will be freed. Each attached vgroup must be detached by calling this routine before the file is closed. **Vdetach** also updates the vgroup information in the HDF file if any changes occur. The identifier $vgroup_id$ should not be used after the vgroup is

detached.

FORTRAN integer function vfdtch(vgroup_id)

integer vgroup_id

HDF Reference Manual Vend/vfend

Vend/vfend

intn Vend(int32 file_id)

file_id IN: File identifier returned by **Hopen**

Purpose Terminates access to a vgroup and/or vdata interface.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description Vend terminates access to the vgroup and/or vdata interfaces initiated by

Vstart and all internal data structures allocated by Vstart.

Vend must be called after all vdata and vgroup operations on the file *file_id* are completed. Further attempts to use vdata or vgroup routines after calling **Vend**

will result in a FAIL (or -1) being returned.

FORTRAN integer function vfend(file_id)

 ${\tt integer\ file_id}$

Vfind/vfind

int32 Vfind(int32 file_id, char *vgroup_name)

file_id IN: File identifier returned by **Hopen**

vgroup_name IN: Name of the vgroup

Purpose Returns the reference number of a vgroup given its name.

Return value Returns the reference number of the vgroup if successful and 0 otherwise.

Description Vfind searches the file identified by the parameter *file_id* for a vgroup with the

name specified by the parameter vgroup_name, and returns the corresponding

reference number.

If more than one vgroup has the same name, Vfind will return the reference

number of the first one.

FORTRAN integer function vfind(file_id, vgroup_name)

integer file_id

character*(*) vgroup_name

Vfindattr/vffdatt

intn Vfindattr(int32 vgroup_id, char *attr_name)

vgroup_id IN: Vgroup identifier returned by Vattach

attr_name IN: Name of the attribute

Purpose Returns the index of a vgroup attribute given its name.

Return value Returns the index of an attribute if successful and FAIL (or -1) otherwise.

Description Vfindattr searches the vgroup identified by the parameter vgroup_id for the

attribute with the name specified by the parameter attr_name, and returns the

index of that attribute.

If more than one attribute has the same name, Vfindattr will return the index

of the first one.

FORTRAN integer function vffdatt(vgroup_id, attr_name)

integer vgroup_id

character*(*) attr_name

Vfindclass/vfndcls

int32 Vfindclass(int32 file_id, char *vgroup_class)

file_id IN: File identifier returned by **Hopen**

vgroup_class IN: Class name of the vgroup

Purpose Returns the reference number of a vgroup specified by its class name.

Return value Returns the reference number of the vgroup if successful and 0 otherwise.

Description Vfindclass searches the file identified by the parameter *file_id* for the vgroup

with the class name specified by the parameter vgroup_class, and returns the

reference number of that vgroup.

If more than one vgroup has the same class name, Vfindclass will return the

reference number of the first one.

FORTRAN integer function vfndcls(file_id, vgroup_class)

integer file_id

character*(*) vgroup_class

Vflocate/vffloc

int32 Vflocate(int32 vgroup_id, char *field_name)

vgroup_id IN: Vgroup identifier returned by **Vattach**

field_name_list IN: List of field names

Purpose Locates a vdata in a vgroup given a list of field names.

Return value Returns the reference number of the vdata if successful and FAIL (or -1)

otherwise.

Description Vflocate searches the vgroup identified by the parameter vgroup_id for a vdata

that contains all of the fields listed in the parameter field_name_list. If that

vdata is found, Vflocate will return its reference number.

FORTRAN integer function vffloc(vgroup_id, field_name)

integer vgroup_id

character*(*) field_name

Vgetattr/vfgnatt/vfgcatt

intn Vgetattr(int32 *vgroup_id*, intn *attr_index*, VOIDP *attr_values*)

vgroup_id IN: Vgroup identifier returned by Vattach

attr_index IN: Index of the attribute

attr_values OUT: Buffer for the attribute values

Purpose Retrieves the values of a vgroup attribute.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description Vgetattr retrieves the values of the attribute identified by its index, attr_index,

into the buffer attr_values for the vgroup identified by the parameter

vgroup_id.

The valid values of the parameter *attr_index* range from 0 to the total number of vgroup attributes - 1. The total number of attributes can be obtained using **Vnattrs**. To determine the amount of memory sufficient to hold the attribute values, the user can obtain the number of attribute values and the attribute

value size using Vattrinfo.

Vgetclass/vfgcls

int32 Vgetclass(int32 vgroup_id, char *vgroup_class)

vgroup_id IN: Vgroup identifier returned by **Vattach**

vgroup_class OUT: Class name of the vgroup

Purpose Retrieves the class name of a vgroup.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description Vgetclass retrieves the class name of the vgroup identified by the parameter

vgroup_id in the buffer vgroup_class.

The maximum length of the name is defined by VGNAMELENMAX (or 64).

FORTRAN integer function vfgcls(vgroup_id, vgroup_class)

integer vgroup_id

character*(*) vgroup_class

Vgetid/vfgid

int32 Vgetid(int32 file_id, int32 vgroup_ref)

file_id IN: File identifier returned by **Hopen**

vgroup_ref IN: Reference number of the current vgroup

Purpose Returns the reference number of the next vgroup.

Return value Returns the reference number of the next vgroup if successful and FAIL (or -1)

otherwise.

Description Vgetid sequentially searches the file identified by the parameter file_id and

returns the reference number of the vgroup following the vgroup that has the

reference number specified by the parameter *vgroup_ref*.

The search is initiated by calling this routine with a *vgroup_ref* value of -1. This will return the reference number of the first vgroup in the file. Searching

past the last vgroup in the file will cause **Vgetid** to return FAIL (or -1).

FORTRAN integer function vfgid(file_id, vgroup_ref)

integer file_id, vgroup_ref

Vgetname/vfgnam

int32 Vgetname(int32 vgroup_id, char *vgroup_name)

vgroup_id IN: Vgroup identifier returned by Vattach

vgroup_name OUT: Name of the vgroup

Purpose Retrieves the name of a vgroup.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description Vgetname retrieves the name of the vgroup identified by the parameter

vgroup_id into the buffer vgroup_name. The maximum length of the name is

defined by VGNAMELENMAX (or 64).

FORTRAN integer function vfgnam(vgroup_id, vgroup_name)

integer vgroup_id

Vgetnext/vfgnxt

int32 Vgetnext(int32 vgroup_id, int32 v_ref)

vgroup_id IN: Vgroup identifier returned by Vattach

v_ref IN: Reference number of the vgroup or vdata

Purpose Gets the reference number of the next member (vgroup or vdata only) of a

vgroup.

Return value Returns the reference number of the vgroup or vdata if successful and FAIL (or

-1) otherwise.

Description Vgetnext searches in the vgroup identified by the parameter vgroup_id for the

object following the object specified by its reference number v_ref . Either of the two objects can be a vgroup or a vdata. If v_ref is set to -1, the routine will

return the reference number of the first vgroup or vdata in the vgroup.

Note that this routine only gets a vgroup or a vdata in a vgroup. Vgettagrefs

gets any object in a vgroup.

intn Vgettagref(int32 vgroup_id, int32 index, int32 *tag, int32 *ref)

vgroup_id IN: Vgroup identifier returned by **Vattach**

index IN: Index of the object in the vgroup

tag OUT: Tag of the object

ref OUT: Reference number of the object

Purpose Retrieves the tag/reference number pair of an object given its index within a

vgroup.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description Vgettagref retrieves the tag/reference number pair of the object specified by its index, index, within the vgroup identified by the parameter vgroup_id. Note

that this routine is different from **Vgettagrefs**, which retrieves the tag/

reference number pairs of a number of objects.

The valid values of *index* range from 0 to the total number of objects in the vgroup - 1. The total number of objects in the vgroup can be obtained using

Vinquire.

The tag is stored in the buffer tag and the reference number is stored in the

buffer ref.

FORTRAN integer function vfgttr(vgroup_id, index, tag, ref)

integer vgroup id, index

integer tag, ref

Vgettagrefs/vfgttrs

int32 Vgettagrefs(int32 vgroup_id, int32 tag_array[], int32 ref_array[], int32 num_of_pairs)

vgroup_id IN: Vgroup identifier returned by Vattach

tag_array OUT: Array of tags

ref_array OUT: Array of reference numbers

num_of_pairs IN: Number of tag/reference number pairs

Purpose Retrieves the tag/reference number pairs of the HDF objects belonging to a

vgroup.

Return value Returns the number of tag/reference number pairs obtained from a vgroup if

successful and FAIL (or -1) otherwise.

Description Vgettagrefs retrieves at most num_of_pairs number of tag/reference number

pairs belonging to the vgroup, vgroup_id, and stores them in the buffers

tag_array and ref_array.

The input parameter *num_of_pairs* specifies the maximum number of tag/

reference number pairs to be returned. The size of the arrays, tag_array and

ref_array, must be at least *num_of_pairs*.

FORTRAN integer function vfgttrs(vgroup_id, tag_array, ref_array, num_of_pairs)

integer vgroup_id, num_of_pairs

integer tag_array(*), ref_array(*)

Vgetversion/vfgver

int32 Vgetversion(int32 *vgroup_id*)

vgroup_id IN: Vgroup identifier returned by **Vattach**

Purpose Gets the version of a vgroup.

Return value Returns the vgroup version number if successful, and FAIL (or -1) otherwise.

Description Vgetversion returns the version number of the vgroup identified by the

parameter *vgroup_id*. There are three valid version numbers: vset_old_version (or 2), vset_version (or 3), and vset_new_version (or

4).

VSET_OLD_VERSION is returned when the vgroup is of a version that

corresponds to an HDF library version before version 3.2.

VSET_VERSION is returned when the vgroup is of a version that corresponds to

an HDF library version between versions 3.2 and 4.0 release 2.

VSET_NEW_VERSION is returned when the vgroup is of the version that

corresponds to an HDF library version of version 4.1 release 1 or higher.

FORTRAN integer function vfgver(vgroup_id)

integer vgroup_id

Vinqtagref/vfinqtr

intn Vinqtagref(int32 vgroup_id, int32 tag, int32 ref)

vgroup_id IN: Vgroup identifier returned by Vattach

tag IN: Tag of the object

ref IN: Reference number of the object

Purpose Checks whether an object belongs to a vgroup.

Return value Returns TRUE (or 1) if the object belongs to the vgroup, and FALSE (or 0)

otherwise.

Description Vinqtagref checks if the object identified by its tag, tag, and its reference

number, *ref*, belongs to the vgroup identified by the parameter *vgroup_id*.

FORTRAN integer function vfinqtr(vgroup_id, tag, ref)

integer vgroup_id, tag, ref

Vinquire/vfinq

intn Vinquire(int32 *vgroup_id*, int32 **n_entries*, char **vgroup_name*)

vgroup_id IN: Vgroup identifier returned by **Vattach**

n_entries OUT: Number of entries in a vgroup

vgroup_name OUT: Name of a vgroup

Purpose Retrieves the number of entries in a vgroup and its name.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description Vinquire retrieves the name of and the number of entries in the vgroup

identified by the parameter vgroup_id into the buffer vgroup_name and the

parameter *n_entries*, respectively.

The maximum length of the vgroup name is defined by VGNAMELENMAX (or 64).

FORTRAN integer function vfinq(vgroup_id, n_entries, vgroup_name)

integer vgroup_id, n_entries
character*(*) vgroup_name

Vinsert/vfinsrt

int32 Vinsert(int32 vgroup_id, int32 v_id)

vgroup_id IN: Vgroup identifier returned by **Vattach**

v_id IN: Identifier of the vdata or vgroup

Purpose Inserts a vdata or vgroup into a vgroup.

Return value Returns the position (index) of the inserted element within the vgroup if

successful and FAIL (or -1) otherwise.

Description Vinsert inserts the vdata or vgroup identified by the parameter v_i into the

vgroup identified by the parameter *vgroup_id*.

Essentially, Vinsert only inserts a vgroup or vdata. To insert any objects into a

vgroup, use Vaddtagref.

The returned value, index, is either 0 or a positive value, which indicates the

position of the inserted element in the vgroup.

FORTRAN integer function vfinsrt(vgroup_id, v_id)

integer vgroup_id, v_id

Visvg/vfisvg

intn Visvg(int32 vgroup_id, int32 obj_ref)

vgroup_id IN: Vgroup identifier returned by Vattach

obj_ref IN: Reference number of the object

Purpose Determines whether an element of a vgroup is a vgroup and a member of

another vgroup.

Return value Returns TRUE (or 1) if the object is a vgroup and FALSE (or 0) otherwise.

Description Visvg determines if the object specified by the reference number, *obj_ref*, is a

vgroup within the vgroup identified by the parameter vgroup_id.

FORTRAN integer function vfisvg(vgroup_id, obj_ref)

integer vgroup_id, obj_ref

Visvs/vfisvs

intn Visvs(int32 vgroup_id, int32 obj_ref)

vgroup_id IN: Vgroup identifier returned by **Vattach**

obj_ref IN: Reference number of the object

Purpose Determines whether a data object is a vdata within a vgroup.

Return value Returns TRUE (or 1) if the object is a vdata and FALSE (or 0) otherwise.

Description Visvs determines if the object specified by the reference number, *obj_ref*, is a

vdata within the vgroup identified by the parameter vgroup_id.

FORTRAN integer function vfisvs(vgroup_id, obj_ref)

integer vgroup_id, obj_ref

HDF Reference Manual Vlone/vflone

Vlone/vflone

int32 Vlone(int32 *file_id*, int32 *ref_array*[], int32 *max_refs*)

file_id IN: File identifier returned by **Hopen**

ref_array OUT: Array of reference numbers

max_refs IN: Maximum number of lone vgroups to be retrieved

Purpose Retrieves the reference numbers of lone vgroups, i.e., vgroups that are at the

top of the grouping hierarchy, in a file.

Return value Returns the total number of lone vgroups if successful and FAIL (or -1)

otherwise.

Description Vlone retrieves the reference numbers of lone vgroups in the file identified by

the parameter *file_id*. Although **Vlone** returns the total number of lone vgroups in the file, only at most *max_refs* reference numbers are retrieved and stored in the buffer *ref_array*. The array must have at least *max_refs* elements.

An array size of 65,000 integers for *ref_array* is more than adequate if the user chooses to declare the array statically. However, the preferred method is to dynamically allocate memory instead; first call **Vlone** with a value of 0 for *max_refs*, and then use the returned value to allocate memory for *ref_array*

before calling **Vlone** again.

FORTRAN integer function vflone(file_id, ref_array, max_refs)

integer file_id, ref_array(*), max_refs

Vnattrs/vfnatts

intn Vnattrs(int32 vgroup_id)

vgroup_id IN: Vgroup identifier returned by Vattach

Purpose Returns the number of attributes assigned to a vgroup.

Return value Returns the total number of attributes assigned to the specified vgroups if

successful and FAIL (or -1) otherwise.

Description Vnattrs gets the number of attributes assigned to the vgroup identified by the

parameter *vgroup_id*.

FORTRAN integer function vfnatts(vgroup_id)

integer vgroup_id

HDF Reference Manual Vnrefs/vnrefs

Vnrefs/vnrefs

int32 Vnrefs(int32 *vgroup_id*, int32 *tag_type*)

vgroup_id IN: Vgroup identifier returned by Vattach

tag_type IN: Type of the tag

Purpose Returns the number of tags of a given tag type in a vgroup.

Return value Returns 0 or the total number of tags if successful and FAIL (or -1) otherwise.

Description Vnrefs returns 0 or the number of tags having the type specified by the

parameter *tag_type* in the vgroup identified by the parameter *vgroup_id*.

See Appendix A, NCSA HDF Tags, in the HDF User's Guide, for a discussion

of tag types.

FORTRAN integer function vnrefs(vgroup_id, tag_type)

integer vgroup_id, tag_type

Vntagrefs/vfntr

int32 Vntagrefs(int32 vgroup_id)

vgroup_id IN: Vgroup identifier returned by **Vattach**

Purpose Returns the number of objects in a vgroup.

Return value Returns 0 or a positive number representing the number of HDF objects linked

to the vgroup if successful or FAIL (or -1) otherwise.

Description Vntagrefs returns the number of objects in a vgroup identified by the

parameter *vgroup_id*.

Vntagrefs is used together with Vgettagrefs, or with Vgettagref to look at the

data objects linked to a given vgroup.

FORTRAN integer function vfntr(vgroup_id)

integer vgroup_id

Vsetattr/vfsnatt/vfscatt

intn Vsetattr(int32 vgroup_id, char *attr_name, int32 data_type, int32 count, VOIDP values)

vgroup_id IN: Vgroup identifier returned by **Vattach**

attr_name IN: Name of the attribute

data_type IN: Data type of the attribute

count IN: Number of values the attribute contains

values IN: Buffer containing the attribute values

Purpose Attaches an attribute to a vgroup.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description

Vsetattr attaches an attribute to the vgroup identified by the parameter *vgroup_id*. The attribute name is specified by the parameter *attr_name* and the attribute data type is specified by the parameter *data_type*. The values of the attribute are specified by the parameter *values*, and the number of values in the attribute is specified by the parameter *count*. Refer to Table 1A in Section I of this manual for a listing of all valid data types.

If the attribute already exists, the new values will replace the current ones, provided the data type and the number of attribute values have not been changed. If either the data type or the order have been changed, **Vsetattr** will return FAIL (or -1).

```
FORTRAN
```

```
integer vfsnatt(vgroup_id, attr_name, data_type, count, values)
```

integer vgroup_id, data_type, count
<valid numeric data type> values(*)

character*(*) attr_name

integer vfscatt(vgroup_id, attr_name, data_type, count, values)

integer vgroup_id, data_type, count
character*(*) attr name, values(*)

Vsetclass/vfscls

int32 Vsetclass(int32 vgroup_id, char *vgroup_class)

vgroup_id IN: Vgroup identifier returned by Vattach

vgroup_class IN: Class name of a vgroup

Purpose Sets the class name of a vgroup.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description Vsetclass sets the class name specified by the parameter vgroup_class to the

vgroup identified by the parameter *vgroup_id*.

A vgroup initially has a class name of NULL. The class name may be set more than once. Class names, like vgroup names, can be of any character strings.

They exist solely as meaningful labels for user applications.

The class name is limited to VSNAMELENMAX (or 64) characters.

FORTRAN integer function vfscls(vgroup_id, vgroup_class)

integer vgroup_id

character*(*) vgroup_class

Vsetname/vfsnam

int32 Vsetname(int32 *vgroup_id*, char **vgroup_name*)

vgroup_id IN: Vgroup identifier returned by **Vattach**

vgroup_name IN: Name of a vgroup

Purpose Sets the name of a vgroup.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description Vsetname sets the name specified by the parameter vgroup_name for the

vgroup identified by the parameter vgroup_id.

A vgroup initially has a name of NULL, and may be renamed more than once during the scope of the vgroup identifier (*vgroup_id*). Note that the routine does not check for uniqueness of vgroup names.

Vgroup names are optional, but recommended. They serve as meaningful labels for user applications. If used, they should be unique. The name length is

limited to VSNAMELENMAX (or 64) characters.

FORTRAN integer function vfsnam(vgroup_id, vgroup_name)

integer vgroup_id

character*(*) vgroup_name

Vstart/vfstart

intn Vstart(int32 file_id)

file_id IN: File identifier returned by **Hopen**

Purpose Initializes the vdata and/or vgroup interface.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description Vstart initializes the vdata and/or vgroup interfaces for the file identified by

the parameter file_id.

Vstart must be called before any vdata or vgroup operation is attempted on an HDF file. **Vstart** must be called once for each file involved in the operation.

FORTRAN integer function vfstart(file_id)

integer file_id

VHmakegroup/vhfmkgp

int32 VHmakegroup(int32 *file_id*, int32 *tag_array*[], int32 *ref_array*[], int32 *n_objects*, char *vgroup_name, char *vgroup_class)

file_id IN: File identifier returned by **Hopen**

tag_array IN: Array of tags

ref_array IN: Array of reference numbers

n_objects IN: Number of data objects to be stored

 vgroup_name
 IN:
 Name of the vgroup

 vgroup_class
 IN:
 Class of the vgroup

Purpose Creates a vgroup.

Return value Returns the reference number of the newly-created vgroup if successful, fail

(or -1) otherwise.

Description VHmakegroup creates a vgroup with the name specified by the parameter vgroup, name and the class name specified by the parameter vgroup, class in

vgroup_name and the class name specified by the parameter vgroup_class in the file identified by the parameter file_id. The routine inserts n_objects objects into the vgroup. The tag and reference numbers of the objects to be

inserted are specified in the arrays tag_array and ref_array.

Creating empty vgroups with **VHmakegroup** is allowed. **VHmakegroup** does not check if the tag/reference number pair is valid, or if the corresponding data object exists. However, all of the tag/reference number pairs must be unique.

Vstart must precede any calls to **VHmakegroup**. It is not necessary, however, to call **Vattach** or **Vdetach** in conjunction with **VHmakegroup**.

The elements in the arrays tag_array and ref_array are the matching tag/reference number pairs of the objects to be inserted, that means $tag_array[0]$ and $ref_array[0]$ refer to one data object, and $tag_array[1]$ and $ref_array[1]$ to another, etc.

FORTRAN integer function vhfmkgp(file_id, tag_array, ref_array, n_objects, vgroup_name, vgroup_class)

integer file_id, n_objects

character*(*) vgroup_name, vgroup_class

integer tag_array(*), ref_array(*)

VQueryref/vqref

int32 VQueryref(int32 vgroup_id)

vgroup_id IN: Vgroup identifier returned by **Vattach**

Purpose Returns the reference number of a vgroup.

Return value Returns the reference number if successful, and FAIL (or -1) otherwise.

Description VQueryref returns the reference number of the vgroup identified by the

parameter *vgroup_id*.

FORTRAN integer function vqref(vgroup_id)

integer vgroup_id

VQuerytag/vqtag

int32 VQuerytag(int32 vgroup_id)

vgroup_id IN: Vgroup identifier returned by **Vattach**

Purpose Returns the tag of a vgroup.

Return value Returns the tag if successful, and FAIL (or -1) otherwise.

Description VQuerytag returns the tag of the vgroup identified by the parameter

vgroup_id.

FORTRAN integer function vqtag(vgroup_id)

integer vgroup_id

VFfieldesize/vffesiz

int32 VFfieldesize(int32 *vdata_id*, int32 *field_index*)

vdata_id IN: Vdata identifier returned by **VSattach**

field_index IN: Vdata field index

Purpose Returns the size, as stored on disk, of a vdata field.

Return value Returns the vdata field size if successful and FAIL (or -1) otherwise.

Description VFfieldesize returns the size, as stored on disk, of a vdata field identified by

the parameter *field_index* in the vdata identified by the parameter *vdata_id*.

The value of the parameter *field_index* ranges from 0 to the total number of fields in the vdata - 1. The number of vdata fields is returned by **VFnfields**

function.

FORTRAN integer function vffesiz(vdata_id, field_index)

integer vdata_id, field_index

VFfieldisize/vffisiz

int32 VFfieldisize(int32 vdata_id, int32 field_index)

vdata_id IN: Vdata identifier returned by **VSattach**

field_index IN: Vdata field index

Purpose Returns the size, as stored in memory, of a vdata field.

Return value Returns the vdata field size if successful and FAIL (or -1) otherwise.

Description VFfieldisize returns the size, as stored in memory, of a vdata field identified by

the parameter *field_index* in the vdata identified by the parameter *vdata_id*.

The value of the parameter *field_index* ranges from 0 to the total number of fields in the vdata - 1. The number of vdata fields is returned by **VFnfields**

function.

FORTRAN integer function vffisiz(vdata_id, field_index)

integer vdata_id, field_index

VFfieldname/vffname

char *VFfieldname(int32 vdata_id, int32 field_index)

vdata_id IN: Vdata identifier returned by **VSattach**

field_index IN: Vdata field index

Purpose Returns the name of a vdata field.

Return value Returns a pointer to the vdata field name if successful and NULL otherwise. The

FORTRAN-77 version of this routine, vffname, returns Succeed (or 0) or fail

(or -1).

Description VFfieldname returns the name of the vdata field identified by the parameter

field_index in the vdata identified by the parameter *vdata_id*.

The value of the parameter *field_index* ranges from 0 to the total number of fields in the vdata - 1. The number of vdata fields is returned by **VFnfields**

function.

The FORTRAN-77 version of this routine, vffname, returns the field name in

the parameter fname.

FORTRAN integer function vffname(vdata_id, field_index, fname)

integer vdata_id, field_index

character*(*) fname

VFfieldorder/vffordr

int32 VFfieldorder(int32 vdata_id, int32 field_index)

vdata_id IN: Vdata identifier returned by **VSattach**

field_index IN: Vdata field index

Purpose Returns the order of a vdata field.

Return value Returns the order of the field if successful and FAIL (or -1) otherwise.

Description VFfieldorder returns the order of the vdata field identified by its index,

field_index, in the vdata identified by the parameter *vdata_id*.

The value of the parameter *field_index* ranges from 0 to the total number of fields in the vdata - 1. The number of vdata fields is returned by **VFnfields**

function.

FORTRAN integer function vffordr(vdata_id, field_index)

integer vdata_id, field_index

VFfieldtype/vfftype

int32 VFfieldtype(int32 vdata_id, int32 field_index)

vdata_id IN: Vdata identifier returned by **VSattach**

field_index IN: Vdata field index

Purpose Returns the data type of a vdata field.

Return value Returns the data type if successful and FAIL (or -1) otherwise.

Description VFfieldtype returns the data type of the vdata field identified by its index,

field_index, in the vdata identified by the parameter *vdata_id*.

The value of the parameter *field_index* ranges from 0 to the total number of fields in the vdata - 1. The number of vdata fields is returned by **VFnfields**

function.

FORTRAN integer function vfftype(vdata_id, field_index)

integer vdata_id, field_index

VFnfields/vfnflds

int32 VFnfields(int32 vdata_id)

vdata_id IN: Vdata identifier returned by **VSattach**

Purpose Returns the total number of fields in a vdata.

Return value Returns the total number of fields if successful and FAIL (or -1) otherwise.

Description VFnfields returns the total number of fields in the vdata identified by the

parameter vdata_id.

FORTRAN integer function vfnflds(vdata_id)

integer vdata_id

VSQuerycount/vsqfnelt

intn VSQuerycount(int32 *vdata_id*, int32 **n_records*)

vdata_id IN: Vdata access identifier returned by VSattach

n_records OUT: Number of records in the vdata

Purpose Retrieves the number of records in a vdata.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description VSQuerycount retrieves the number of records in the vdata identified by

vdata_id in the parameter *n_records*.

FORTRAN integer function vsqfnelt(vdata_id, n_records)

integer vdata_id, n_records

VSQueryfields/vsqfflds

intn VSQueryfields(int32 vdata_id, char *field_name_list)

vdata_id IN: Vdata access identifier returned by **VSattach**

field_name_list OUT: List of field names

Purpose Retrieves the names of the fields in a vdata.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description VSQueryfields retrieves the names of the fields in the vdata identified by the

parameter *vdata_id* into the parameter *field_name_list*.

The parameter field_name_list is a comma-separated list of the fields in the

vdata. (i.e., "PX,PY,PZ" in C and 'PX,PY,PZ' in Fortran).

FORTRAN integer function vsqfflds(vdata_id, field_name_list)

integer vdata_id

character*(*) field_name_list

VSQueryinterlace/vsqfintr

intn VSQueryinterlace(int32 vdata_id, int32 *interlace_mode)

vdata_id IN: Vdata identifier returned by **VSattach**

interlace_mode OUT: Interlace mode

Purpose Retrieves the interlace mode of the vdata.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description VSQueryinterlace retrieves the interlace mode of the vdata identified by the

parameter *vdata_id* into the parameter *interlace_mode*.

Valid values for interlace_mode are full_interlace (or 0) and no_interlace

(or 1)

FORTRAN integer function vsqfintr(vdata_id, interlace_mode)

integer vdata_id, interlace_mode

VSQueryname/vsqfname

intn VSQueryname(int32 vdata_id, char *vdata_name)

vdata_id IN: Vdata identifier returned by **VSattach**

vdata_name OUT: Name of the vdata

Purpose Retrieves the name of a vdata.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description VSQueryname retrieves the name of the vdata identified by the parameter

vdata_id into the buffer *vdata_name*.

The buffer vdata_name should be set to at least VSNAMELENMAX bytes.

VSNAMELENMAX is defined by the HDF library.

FORTRAN integer function vsqfname(vdata_id, vdata_name)

integer vdata_id

character*(*) vdata_name

VSQueryref/vsqref

int32 VSQueryref(int32 vdata_id)

vdata_id IN: Vdata identifier returned by **VSattach**

Purpose Returns the reference number of a vdata.

Return value Returns the reference number of the vdata if successful and FAIL (or -1)

otherwise.

Description VSQueryref returns the reference number of the vdata identified by the

parameter *vdata_id*.

FORTRAN integer function vsqref(vdata_id)

integer vdata_id

VSQuerytag/vsqtag

int32 VSQuerytag(int32 vdata_id)

vdata_id IN: Vdata identifier returned by **VSattach**

Purpose Returns the tag of the specified vdata.

Return value Returns the tag of the vdata if successful and FAIL (or -1) otherwise.

Description Returns the tag of the vdata identified by the parameter *vdata_id*.

FORTRAN integer function vsqtag(vdata_id)

integer vdata_id

VSQueryvsize/vsqfvsiz

intn VSQueryvsize(int32 vdata_id, int32 *vdata_size)

vdata_id IN: Vdata identifier returned by **VSattach**

vdata_size OUT: Size of the vdata record

Purpose Retrieves the size of a record in a vdata.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description VSQueryvsize retrieves the size, in bytes, of a record in the vdata identified by

the parameter vdata_id into the parameter vdata_size. The returned size value

is machine dependent.

FORTRAN integer function vsqfvsiz(vdata_id, vdata_size)

integer vdata_id, vdata_size

VHstoredata/vhfsd/vhfscd

int32 VHstoredata(int32 file_id, char *fieldname, uint8 buf[], int32 n_records, int32 data_type, char *vdata_name, char *vdata_class)

file_id IN: File identifier returned by **Hopen**

fieldname IN: Field name for the new vdata

buf IN: Buffer containing the records to be stored

n_records IN: Number of records to be stored

data_type IN: Type of data to be stored

 vdata_name
 IN:
 Name of the vdata to be created

 vdata class
 IN
 Class of the vdata to be created

Purpose Creates and writes to a single-field vdata.

Return value Returns reference number of the newly-created vdata if successful, and FAIL

(or -1) otherwise.

Description VHstoredata creates a single-field vdata in the file, *file_id*, and stores data from the buffer *buf* in it. Vdata name, class name and data type are specified by

the parameters *vdata_name*, *vdata_class*, and *data_type*, respectively. Number of records in a vdata is specified by the parameter *n_records*. Field name is

specified by the parameter *fieldname*.

Vstart must precede VHstoredata. It is not necessary, however, to call VSattach or VSdetach in conjunction with VHstoredata.

This routine provides a high-level method for creating single-order, single-field vdatas.

Note that there are two FORTRAN-77 versions of this routine; one for numeric data (**vhfsd**) and the other for character data (**vhfsdc**).

FORTRAN integer function vhfsd(file_id, fieldname, buf, n_records,

data_type, vdata_name, vdata_class)

integer file_id, n_records, data_type

character*(*) vdata_name, vdata_class, fieldname

<valid numeric data type> buf(*)

integer file_id, n_records, data_type

character*(*) vdata_name, vdata_class, fieldname
character*(*) buf

VHstoredatam/vhfsdm/vhfscdm

int32 VHstoredatam(int32 file_id, char *fieldname, uint8 buf[], int32 n_records, int32 data_type, char *vdata name, char *vdata class, int32 order)

file_id IN: File identifier returned by **Hopen**

fieldname IN: Field name

buf IN: Buffer containing the records to be stored

n_records IN: Number of records to be stored

data_type IN: Type of data to be stored

vdata_nameIN:Name of the vdata to be createdvdata_classIN:Class of the vdata to be created

order IN: Field order

Purpose Creates and writes to a multi-order, single-field vdata.

Return value Returns the reference number of the newly created vdata if successful, and

FAIL (or -1) otherwise.

Description VHstoredatam creates a vdata with the name specified by the parameter vdata class name specified by the parameter vdata class in the file

vdata_name and a class name specified by the parameter vdata_class in the file identified by the parameter file_id. The data type of the vdata is specified by the parameter data_type. The vdata contains one field with the name specified by the parameter fieldname. The order of the field, order, indicates the number of vdata values stored per field. The vdata contains the number of records specified by the parameter n_records. The buf parameter should contain

 $n_{records}$ records that will be stored in the vdata.

Vstart must precede VHstoredatam. It is not necessary, however, to call VSattach or VSdetach in conjunction with VHstoredatam.

This routine provides a high-level method for creating multi-order, single-field vdatas.

Note that there are two FORTRAN-77 versions of this routine; one for numeric data (**vhfsdm**) and the other for character data (**vhfsdm**).

FORTRAN integer function vhfsdm(file_id, fieldname, buf, n_records,

integer file_id, n_records, data_type, order

character*(*) vdata_name, vdata_class, fieldname

<valid numeric data type> buf(*)

VSappendable/vsapp (Obsolete)

int32 VSappendable(int32 vdata_id, int32 block_size)

vdata_id IN: Vdata identifier returned by **VSattach**

block_size IN: Standard block size of appended data

Purpose Makes it possible to append to a vdata.

Return value Retrieves SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description The HDF library makes all vdatas appendable upon creation. Therefore, this

routine has been made obsolete.

FORTRAN integer function vsapp(vdata_id, block_size)

integer vdata_id, block_size

VSattach/vsfatch

int32 VSattach(int32 file_id, int32 vdata_ref, char *access)

file_id IN: File identifier returned by **Hopen**

vdata_ref IN: Reference number of the vdata

access IN: Access mode

Purpose Attaches to an existing vdata or creates a new vdata.

Return value Returns a vdata identifier if successful and FAIL (or -1) otherwise.

Description

VSattach attaches to the vdata identified by the reference number, *vdata_ref*, in the file identified by the parameter *file_id*. Access to the vdata is specified by the parameter *access*. **VSattach** returns an identifier to the vdata, through which all further operations on that vdata are carried out.

An existing vdata may be multiply-attached for reads. Only one attach with write access to a vdata is allowed.

The default interlace mode for a new vdata is FULL_INTERLACE (or 0). This may be changed using **VSsetinterlace**.

The value of the parameter *vdata_ref* may be -1. This is used to create a new vdata.

Valid values for access are "r" for read access and "w" for write access.

If *access* is "r", then *vdata_ref* must be the valid reference number of an existing vdata returned from any of the vdata and vgroup search routines (e.g., **Vgetnext** or **VSgetid**). It is an error to attach to a vdata with a *vdata_ref* of -1 with "r" access.

If *access* is "w", then *vdata_ref* must be the valid reference number of an existing vdata or -1. An existing vdata is generally attached with "w" access to replace part of its data, or to append new data to it.

FORTRAN integer function vsfatch(file_id, vdata_ref, access)

integer file_id, vdata_ref

character*1 access

VSattrinfo/vsfainf

intn VSattrinfo(int32 *vdata_id*, int32 *field_index*, intn *attr_index*, char *attr_name, int32 *data_type, int32 *count, int32 *size)

IN: Vdata identifier returned by VSattach vdata_id field_index IN: Index of the field IN: Index of the attribute attr_index Name of the attribute attr_name OUT: OUT: Data type of the attribute data_type OUT: Attribute value count count OUT: Size of the attribute size

Purpose Retrieves attribute information of a vdata or a vdata field.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description VSattrinfo gets information on the attribute attached to the vdata, vdata_id, or

to the vdata field. Vdata field is specified by its index, *field_index*. Attribute is specified by its index, *attr_index*. The attribute name is returned into the parameter *attr_name*, the data type is returned into the parameter *data_type*, the number of values of the attribute is returned into the parameter *count*, and

the size of the attribute is returned into the parameter *size*.

The parameter *field_index* in **VSattrinfo** is the same as the parameter *field_index* in **VSsetattr**. It can be set to either an integer field index for the vdata field attribute, or _HDF_VDATA (or -1) to specify the vdata attribute.

In C the values of the parameters *attr_name*, *data_type*, *count* and *size* can be set to NULL if the information returned by these parameters is not needed.

FORTRAN integer function vsfainf(vdata_id, field_index, attr_index, attr_name, data_type, count, size)

integer vdata_id, field_index, attr_index

character*(*) attr_name

integer data_type, count, size

VSdelete/vsfdlte

int32 VSdelete(int32 file_id, int32 vdata_ref)

file_id IN: File identifier returned by **Hopen**

vdata_ref IN: Vdata reference number returned by VSattach

Purpose Remove a vdata from a file.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) if not successful.

Description VSdelete removes the vdata identified by the parameter *vdata_ref* from the file

identified by the parameter *file_id*.

FORTRAN integer function vsfdlte(file_id, vdata_ref)

integer file_id, vdata_ref

VSdetach/vsfdtch

int32 VSdetach(int32 vdata_id)

vdata_id IN: Vdata identifier returned by **VSattach**

Purpose Detaches from the current vdata, terminating further access to that vdata.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description VSdetach detaches from the vdata identified by the parameter vdata_id and

updates the vdata information in the file if there are any changes. All memory

used for that vdata is freed.

The *vdata_id* identifier should not be used after that vdata is detached.

FORTRAN integer function vsfdtch(vdata_id)

integer vdata_id

VSelts/vsfelts

int32 VSelts(int32 vdata_id)

vdata_id IN: Vdata identifier returned by **VSattach**

Purpose Determines the number of records in a vdata.

Return value Returns the number of records in the vdata if successful and FAIL (or -1)

otherwise.

Description VSelts returns the number of records in the vdata identified by *vdata_id*.

FORTRAN integer function vsfelts(vdata_id)

integer vdata_id

VSfdefine/vsffdef

intn VSfdefine(int32 vdata_id, char *fieldname, int32 data_type, int32 order)

vdata_id IN: Vdata identifier returned by **VSattach**

fieldname IN: Name of the field to be defined

data_type IN: Data type of the field values

order IN: Order of the new field

Purpose Defines a new field for in a vdata.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description

VSfdefine defines a field with the name specified by the parameter *fieldname*, of the data type specified by the parameter *data_type*, of the order specified by the parameter *order*, and within the vdata identified by the parameter *vdata_id*.

VSfdefine is only used to define fields in a new vdata; it does not set the format of a vdata. Note that defining a field using **VSfdefine** does not prepare the storage format of the vdata. Once the fields have been defined, the routine **VSsetfields** must be used to set the format. **VSfdefine** may only be used with a new empty vdata. Once there is data in a vdata, definitions of vdata fields may not be modified or deleted.

There are certain field names the HDF library recognizes as predefined. A list of these predefined field types can be found in the HDF User's Guide.

A field is defined by its name (*fieldname*), its type (*data_type*) and its order (*order*). A fieldname is any sequence of characters. By convention, fieldnames are usually a mnemonic, e.g. "PRESSURE". The type of a field specifies whether a field is float, integer, etc. Thus, *data_type* may be one of the data types listed in Table 1A in Section I of this manual.

The order of a field is the number of components in that field. A field containing the value of a simple variable, such a time or pressure, would have an order of 1. Compound variables have an order greater than 1. For example, a field containing the values associated with a variable for velocity in three dimensions would have an order of 3.

FORTRAN

```
integer function vsffdef(vdata_id, fieldname, data_type, order)
```

integer vdata_id, data_type, order

character*(*) fieldname

VSfexist/vsfex

intn VSfexist(int32 vdata_id, char *field_name_list)

vdata_id IN: Vdata identifier returned by **VSattach**

field_name_list IN: List of field names

Purpose Checks to see if certain fields exist in the current vdata.

Return value Returns a value of 1 if all field(s) exist and FAIL (or -1) otherwise.

Description VSfexist checks if all fields with the names specified in the parameter

field_name_list exist in the vdata identified by the parameter *vdata_id*.

The parameter field_name_list is a string of comma-separated fieldnames (e.g.,

"PX,PY,PZ" in C and 'PX,PY,PZ' in Fortran).

FORTRAN integer function vsfex(vdata_id, field_name_list)

integer vdata_id

character*(*) field_name_list

HDF Reference Manual VSfind/vsffnd

VSfind/vsffnd

int32 VSfind(int32 file_id, char *vdata_name)

file_id IN: File identifier returned by **Hopen**

vdata_name IN: Name of the vdata

Purpose Returns the reference number of a vdata, given its name.

Return value Returns the vdata reference number if successful and 0 if the vdata is not found

or an error occurs.

Description VSfind returns the reference number of the vdata with the name specified by

the parameter *vdata_name* in the file specified by the parameter *file_id*. If there is more than one vdata with the same name, **VSfind** will only find the

reference number of the first vdata in the file with that name.

FORTRAN integer function vsffnd(file_id, vdata_name)

integer file_id

character*(*) vdata_name

VSfindattr/vsffdat

intn VSfindattr(int32 vdata_id, int32 field_index, char *attr_name)

vdata_id IN: Vdata identifier returned by **VSattach**

field_index IN: Field index

attr_name IN: Attribute name

Purpose Returns the index of an attribute of a vdata or vdata field.

Return value Returns the index of the attribute if successful and FAIL (or -1) otherwise.

Description VSfindattr returns the index of the attribute with the name specified by the

parameter *attr_name* in the vdata identified by the parameter *vdata_id*.

To return the index of the attribute attached to the vdata, set the value of the parameter <code>field_index</code> to <code>_HDF_VDATA</code> (or <code>-1</code>). To return the index of the attribute of a field in the vdata, set the value of the parameter <code>field_index</code> to the field index. Valid values of <code>field_index</code> range from 0 to the total number of the vdata fields - 1. The number of the vdata fields is returned by **VFnfields**.

FORTRAN integer function vsffdat(vdata_id, field_index, attr_name)

integer vdata_id, field_index

character*(*) attr_name

VSfindclass/vffcls

int32 VSfindclass(int32 file_id, char *vdata_class)

file_id IN: File identifier returned by **Hopen**

vdata_class IN: Class of the vdata

Purpose Returns the reference number of the first vdata with a given vdata class name

Return value Returns the reference number of the vdata if successful and 0 if the vdata is not

found or an error occurs.

Description VSfindclass returns the reference number of the vdata with the class name

specified by the parameter *vdata_class* in the file identified by the parameter

file_id.

FORTRAN integer function vffcls(vdata_id, vdata_class)

integer vdata_id

character*(*) vdata_class

VSfindex/vsffidx

intn VSfindex(int32 vdata_id, char *fieldname, int32 *field_index)

vdata_id IN: Vdata identifier returned by **VSattach**

fieldname IN: Name of the field

field_index OUT: Index of the field

Purpose Retrieves the index of a field within a vdata.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description VSfindex retrieves the index, *field_index*, of the field with a name specified by

the parameter fieldname, within the vdata identified by the parameter vdata_id.

FORTRAN integer function vsffidx(vdata_id, fieldname, field_index)

integer vdata_id, field_index

character*(*) fieldname

VSfnattrs/vsffnas

int32 VSfnattrs (int32 *vdata_id*, int32 *field_index*)

vdata_id IN: Vdata identifier returned by **VSattach**

field_index IN: Index of the field

Purpose Returns the number of attributes attached to a vdata *or* the number of attributes

attached to a vdata field.

Return value Returns the number of attributes assigned to this vdata or its fields when

successful, and FAIL (or -1) otherwise.

Description VSfnattrs returns the number of attributes attached to a vdata specified by the

parameter vdata_id, or the number of attributes attached to a vdata field,

specified by the field index, *field_index*.

To return the number of attributes attached to the vdata, set the value of field_index to _HDF_VDATA (or -1). To return the number of attributes of a field in the vdata, set the value of field_index to the field index. Field index is a nonnegative integer less than the total number of the vdata fields. The number

of vdata fields is returned by **VFnfields**.

VSfnattrs is different from the VSnattrs routine, which returns the number of

attributes of the specified vdata and the fields contained in it.

FORTRAN integer function vsffnas(vdata_id, field_index)

integer vdata_id, field_index

VSfpack/vsfcpak/vsfnpak

intn VSfpack(int32 vdata_id, intn action, char *fields_in_buf, VOIDP buf, intn buf_size, intn n_records, char *field_name_list, VOIDP bufptrs[])

vdata_id IN: Vdata identifier returned by **VSattach**

action IN: Action to be performed

fields_in_buf IN: Names of the fields in buf

buf IN/OUT: Buffer containing the values of the packed fields to write to or read

from the vdata

buf_size IN: Buffer size in bytes

n_records IN: Number of records to pack or unpack

field_name_list IN: Names of the fields to be packed or unpacked

bufptrs IN/OUT: Array of pointers to the field buffers

Purpose Packs field data into a buffer or unpacks buffered field data into vdata field(s)

for fully interlaced fields.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description VSfpack packs or unpacks the field(s) listed in the parameter *field_name_list* to or from the buffer *buf* according to the specified action in the parameter

action.

Valid values for action are _hdf_vspack (or 0) which packs field values from bufptrs (the field buffers) to buf, or _hdf_vsunpack (or 1) which unpacks vdata

field values from buf into bufptrs.

When **VSfpack** is called to pack field values into *buf*, *fields_in_buf* must list all fields of the vdata. When **VSfpack** is called to unpack field values, *fields_in_buf* may be a subset of the vdata fields. To specify all vdata fields in *fields_in_buf*, NULL can be used in C and a blank character ("") in Fortran.

The name(s) of the field(s) to be packed or unpacked are specified by the field_name_list. In C, the names in the parameter field_name_list can be a subset of or all field names listed in fields_in_buf. To specify all vdata fields, NULL can be used in C.

The FORTRAN-77 versions of this routine can pack or unpack only one field at a time. Therefore, *field_name_list* will contain the name of the field that will be packed or unpacked.

The calling program must allocate sufficient space for *buf* to hold all of the packed fields. The size of the *buf* buffer should be at least $n_records$ * (the total size of all fields specified in *fields_in_buf*).

Note that there are two FORTRAN-77 versions of this routine: **vsfnpak** to pack or unpack a numeric field and **vsfcpak** to pack or unpack a character field

Refer to the HDF User's Guide for an example on how to use this routine.

FORTRAN

VSgetattr/vsfgnat/vsfgcat

intn VSgetattr(int32 vdata_id, intn field_index, int32 attr_index, VOIDP values)

vdata_id IN: Vdata identifier returned by **VSattach**

field_index IN: Index of the field

attr_index IN: Index of the attribute

values OUT: Buffer for the attribute values

Purpose Retrieves the attribute values of a vdata or vdata field.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

VSgetattr retrieves the attribute values of the vdata identified by the parameter *vdata_id* or the vdata field specified by the field index, *field_index*, into the

buffer values.

If *field_index* is set to _HDF_VDATA (or -1), the value of the attribute attached to the vdata is returned. If *field_index* is set to the field index, attribute attached to a vdata field is returned. Field index is a nonnegative integer less than the total number of the vdata fields. The number of vdata fields is returned by

VFnfields

Attribute to be retrieved is specified by its index, *attr_index*. Index is a nonnegative integer less than the total number of the vdata or vdata field attributes. Use **VSfnattrs** to find the number of the vdata or vdata field attributes.

```
FORTRAN integer function vsfgnat(vdata_id, field_index, attr_index,
```

values)

integer vdata_id, field_index, attr_index

<valid numeric data type> values(*)

integer vdata_id, field_index, attr_index

character*(*) values

VSgetblockinfo/vsfgetblinfo

intn VSgetblockinfo(int32 vdata_id, int32 *block_size, int32 *num_blocks)

vdata_id IN: Vdata identifier

block_size OUT: Block size in bytes

num blocks OUT: Number of linked blocks

Purpose Retrieves the block size and the number of blocks for a linked-block Vdata

element.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description VSgetblockinfo retrieves the block size and the number of linked blocks for a

linked-block Vdata element.

If no response is desired for either returned value, block_size and num_blocks

may be set to NULL.

FORTRAN integer function vsfgetblinfo(vdata_id, block_size, num_blocks)

integer vdata_id, num_blocks, block_size

VSgetclass/vsfgcls

int32 VSgetclass(int32 vdata_id, char *vdata_class)

vdata_id IN: Vdata identifier returned by **VSattach**

vdata_class OUT: Vdata class name

Purpose Retrieves the vdata class name, if any.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description VSgetclass retrieves the class name of the vdata identified by the parameter

vdata_id and places it in the buffer *vdata_class*.

Space for the buffer *vdata_class* must be allocated by the calling program before **VSgetclass** is called. The maximum length of the class name is defined

by the macro vsnamelenmax (or 64).

FORTRAN integer function vsfgcls(vdata_id, vdata_class)

integer vdata_id

character*(*) vdata_class

VSgetfields/vsfgfld

int32 VSgetfields(int32 *vdata_id*, char *field_name_list)

vdata_id IN: Vdata identifier returned by **VSattach**

field_name_list OUT: Field name list

Purpose Retrieves the field names of all of the fields in a Vdata.

Return value Returns the number of fields in the Vdata if successful and FAIL (or -1)

otherwise.

Description VSgetfields retrieves the names of the fields in the Vdata identified by the

parameter *vdata_id* into the buffer *field_name_list*.

The parameter *field_name_list* is a character string containing a commaseparated list of names (e.g., "PX,PY,PZ" in C or 'PX,PY,PZ' in Fortran).

The user must allocate the memory space for the buffer field_name_list before

calling VSgetfields.

If the Vdata does not have any fields, a null string is returned in the parameter

field_name_list.

The maximum length of a Vdata name is defined by VSNAMELENMAX (or 64).

FORTRAN integer function vsfgfld(vdata_id, field_name_list)

integer vdata_id

character*(*) field_name_list

VSgetid/vsfgid

int32 VSgetid(int32 file_id, int32 vdata_ref)

file_id IN: File identifier returned by **Hopen**

vdata_ref IN: Vdata reference number

Purpose Sequentially searches through a file for vdatas.

Return value Returns the reference number for the next vdata if successful and FAIL (or -1)

otherwise.

Description VSgetid sequentially searches through a file identified by the parameter *file_id*

and returns the reference number of the next vdata after the vdata that has reference number *vdata_ref*. This routine is generally used to sequentially search the file for vdatas. Searching past the last vdata in a file will result in an

error condition.

To initiate a search, this routine must be called with the value of *vdata_ref* equal to -1. Doing so returns the reference number of the first vdata in the file.

FORTRAN integer function vsfgid(file_id, vdata_ref)

integer file_id, vdata_ref

VSgetinterlace/vsfgint

int32 VSgetinterlace(int32 *vdata_id*)

vdata_id IN: Vdata identifier returned by **VSattach**

Purpose Returns the interlace mode of a vdata.

Return value Returns full_interlace (or 0) or no_interlace (or 1) if successful and fail

(or -1) otherwise.

Description VSgetinterlace returns the interlace mode of the vdata identified by the

parameter *vdata_id*.

FORTRAN integer function vsfgint(vdata_id)

integer vdata_id

VSgetname/vsfgnam

int32 VSgetname(int32 vdata_id, char *vdata_name)

vdata_id IN: Vdata identifier returned by **VSattach**

vdata_name OUT: Vdata name

Purpose Retrieves the name of a vdata.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description VSgetname retrieves the name of the vdata identified by the parameter

vdata_id into the buffer *vdata_name*.

The user must allocate the memory space for the buffer *vdata_name* before calling **VSgetname**. If the vdata does not have a name, a null string is returned in the parameter *vdata_name*. The maximum length of a vdata name is

defined by vsnamelenmax (or 64)

FORTRAN integer function vsfgnam(vdata_id, vdata_name)

integer vdata_id

character*(*) vdata_name

VSgetversion/vsgver

int32 VSgetversion(int32 vdata_id)

vdata_id IN: Vdata identifier returned by **VSattach**

Purpose Returns the version number of a vdata.

Return value Returns the version number if successful and FAIL (or -1) otherwise.

Description VSgetversion returns the version number of the vdata identified by the

parameter *vdata_id*. There are three valid version numbers: vset_old_version (or 2), vset_version (or 3), and vset_new_version (or 4).

VSET_OLD_VERSION is returned when the vdata is of a version that corresponds

to an HDF library version before version 3.2.

VSET_VERSION is returned when the vdata is of a version that corresponds to an

HDF library version between versions 3.2 and 4.0 release 2.

VSET_NEW_VERSION is returned when the vdata is of the version that corresponds to an HDF library version of version 4.1 release 1 or higher.

FORTRAN integer vsgver(vdata_id)

integer vdata_id

VSinquire/vsfinq

intn VSinquire(int32 *vdata_id*, int32 **n_records*, int32 **interlace_mode*, char **field_name_list*, int32 **vdata_size*, char **vdata_name*)

vdata_id IN: Vdata identifier returned by **VSattach**

n_records OUT: Number of records

interlace_mode OUT: Interlace mode of the data

field_name_list OUT: List of field names

vdata_size OUT: Size of a record

vdata_name OUT: Name of the vdata

Purpose Retrieves general information about a vdata.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) if it is unable to return

any of the requested information.

Description VSinquire retrieves the number of records, the interlace mode of the data, the

name of the fields, the size, and the name of the vdata, *vdata_id*, and stores them in the parameters *n_records*, *interlace_mode*, *field_name_list*, *vdata_size*, and *vdata_name*, respectively. In C, if any of the output parameters are NULL, the corresponding information will not be retrieved. Refer to the Reference Manual pages on **VSelts**, **VSgetfields**, **VSgetinterlace**, **VSsizeof** and **VSgetname** for other routines that can be used to retrieve specific

information.

Possible returned values for *interlace_mode* are <code>full_interlace</code> (or 0) and <code>no_interlace</code> (or 1). The returned value of <code>vdata_size</code> is the number of bytes

in a record and is machine-dependent.

The parameter *field_name_list* is a character string that contains the names of all the vdata fields, separated by commas. (e.g., "PX,PY,PZ" in C and

'PX,PY,PZ' in Fortran).

The user must allocate the memory space for the buffer *vdata_name* before calling **VSinquire**. If the vdata does not have a name, a null string is returned in the parameter *vdata name*. The maximum length of a vdata name is

defined by vsnamelenmax (or 64)

FORTRAN integer function vsfinq(vdata_id, n_records, interlace, field_name_list, vdata_size, vdata_name)

integer vdata_id, n_records, interlace, vdata_size

character*(*) field_name_list, vdata_name

VSisattr/vsfisat

intn VSisattr(int32 vdata_id)

vdata_id IN: Vdata identifier returned by **VSattach**

Purpose Determines whether a vdata is an attribute.

Return value Returns TRUE (or 1) if the vdata is an attribute, and FALSE (or 0) otherwise.

Description VSisattr determines whether the vdata identified by the parameter *vdata_id* is

an attribute.

As attributes are stored by the HDF library as vdatas, a means of testing whether or not a particular vdata is an attribute is needed, and is provided by

this routine.

FORTRAN integer function vsfisat(vdata_id)

 ${\tt integer\ vdata_id}$

VSlone/vsflone

int32 VSlone(int32 *file_id*, int32 *ref_array*[], int32 *maxsize*)

file_id IN: File identifier returned by **Hopen**

ref_array OUT: Array of reference numbers

max refs IN: Maximum number of lone vdatas to be retrieved

Purpose Retrieves the reference numbers of all lone vdatas, i.e., vdatas that are not

grouped with other objects, in a file.

Return value Returns the total number of lone vdatas if successful and FAIL (or -1)

otherwise.

Description VSlone retrieves the reference numbers of lone vgroups in the file identified

by the parameter *file_id*. Although **VSlone** returns the number of lone vdatas in the file, only at most *max_refs* reference numbers are retrieved and stored in

the buffer ref_array. The array must have at least max_refs elements.

An array size of 65,000 integers for *ref_array* is more than adequate if the user chooses to declare the array statically. However, the preferred method is to dynamically allocate memory instead; first call **VSlone** with a value of 0 for *max refs* to return the total number of lone vdatas, then use the returned value

to allocate memory for *ref_array* before calling **VSlone** again.

FORTRAN integer function vsflone(file_id, ref_array, max_refs)

integer file_id, ref_array(*), max_refs

VSnattrs/vsfnats

intn VSnattrs(int32 vdata_id)

vdata_id IN: Vdata identifier returned by **VSattach**

Purpose Returns the total number of attributes of a vdata and of its fields.

Return value Returns the total number of attributes if successful and FAIL (or -1) otherwise.

Description VSnattrs returns the total number of attributes of the vdata, vdata_id, and of

its fields.

VSnattrs is different from the **VSfnattrs** routine, which returns the number of attributes of a specified vdata *or* of a field contained in a specified vdata.

FORTRAN integer function vsfnats(vdata_id)

integer vdata_id

VSread/vsfrdc/vsfread

int32 VSread(int32 vdata_id, uint8 *databuf, int32 n_records, int32 interlace_mode)

vdata id IN: Vdata identifier returned by **VSattach**

databuf OUT: Buffer to store the retrieved data

n_records IN: Number of records to be retrieved

interlace mode IN: Interlace mode of the data to be stored in the buffer

Purpose Retrieves data from a vdata.

Return value Returns the total number of records read if successful and FAIL (or -1)

otherwise.

Description VSread reads *n_records* records from the vdata identified by the parameter *vdata_id* and stores the data in the buffer *databuf* using the interlace mode

specified by the parameter *interlace_mode*.

The user can specify the fields and the order in which they are to be read by calling **VSsetfields** prior to reading. **VSread** stores the requested fields in *databuf* in the specified order.

Valid values for *interlace_mode* are <code>FULL_INTERLACE</code> (or 1) and <code>NO_INTERLACE</code> (or 0). Selecting <code>FULL_INTERLACE</code> causes *databuf* to be filled by record and is recommended for speed and efficiency. Specifying <code>NO_INTERLACE</code> causes *databuf* to be filled by field, i.e., all values of a field in <code>n_records</code> records are filled before moving to the next field. Note that the default interlace mode of the buffer is <code>FULL_INTERLACE</code>.

As the data is stored contiguously in the vdata, **VSfpack** should be used to unpack the fields after reading. Refer to the discussion of **VSfpack** in the HDF User's Guide for more information.

Note that there are three FORTRAN-77 versions of this routine: **vsfrd** is for buffered numeric data, **vsfrdc** is for buffered character data and **vsfread** is for generic packed data.

See the notes regarding the potential performance impact of appendable data sets in the *HDF User's Guide* Section 14.4.3, "Unlimited Dimension Data Sets (SDSs and Vdatas) and Performance."

```
FORTRAN integer function vsfrd(vdata_id, databuf, n_records, interlace_mode)
```

integer vdata_id, n_records, interlace_mode

<valid numeric data type> databuf(*)

VSseek/vsfseek

int32 VSseek(int32 vdata_id, int32 record_pos)

vdata_id IN: Vdata identifier returned by **VSattach**

record_pos IN: Position of the record

Purpose Provides a mechanism for random-access I/O within a vdata.

Return value Returns the record position (zero or a positive integer) if successful and FAIL

(or -1) otherwise.

Description VSseek moves the access pointer within the vdata identified by the parameter

vdata_id to the position of the record specified by the parameter *record_pos*. The next call to **VSread** or **VSwrite** will read from or write to the record where

the access pointer has been moved to.

The value of *record_pos* is zero-based. For example, to seek to the third record in the vdata, set *record_pos* to 2. The first record position is specified by specifying a *record_pos* value of 0. Each seek is constrained to a record

boundary within the vdata.

See the notes regarding the potential performance impact of appendable data sets in the *HDF User's Guide* Section 14.4.3, "Unlimited Dimension Data Sets

(SDSs and Vdatas) and Performance."

FORTRAN integer function vsfseek(vdata_id, record_pos)

integer vdata_id, record_pos

VSsetattr/vsfsnat/vsfscat

intn VSsetattr(int32 vdata_id, int32 field_index, char *attr_name, int32 data_type, int32 count, VOIDP values)

vdata_id IN: Vdata identifier returned by **VSattach**

field_index IN: Index of the field

attr name IN: Name of the attribute

data_type IN: Data type of the attribute

count IN: Number of attribute values

values IN: Buffer containing the attribute values

Purpose Sets an attribute of a vdata or a vdata field.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description

VSsetattr defines an attribute that has the name specified by the parameter *attr_name*, the data type specified by the parameter *data_type*, and the number of values specified by the parameter *count*, and that contains the values specified in the parameter *values*. The attribute is set for either the vdata or a vdata field depending on the value of the parameter *field_index*.

If the field already has an attribute with the same name, the current values will be replaced with the new values if the new data type and order are the same as the current ones. Any changes in the field data type or order will result in a value of FAIL (or -1) to be returned.

If *field_index* value is set to _HDF_VDATA (or -1), the attribute will be set for the vdata. If *field_index* is set to the field index, attribute will be set for the vdata field. Field index is a nonnegative integer less than the total number of the vdata fields. The number of vdata fields can be obtained using **VFnfields**.

The value of the parameter *data_type* can be any one of the data types listed in Table 1A in Section I of this manual.

FORTRAN

VSsetblocksize/vsfsetblsz

intn VSsetblocksize(int32 *vdata_id*, int32 *block_size*)

vdata id IN: Vdata identifier

block_size IN: Size of each block in bytes

Purpose Sets linked-block Vdata element block size.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description VSsetblocksize sets the block size for linked-block elements that will be used to store Vdatas.

The default block size is <code>HDF_APPENDABLE_BLOCK_LEN</code>, which is set to 4096 in the library as it is distributed. **VSsetblocksize** modifies that default value and must be called before the first write to the Vdata. Once the linked-block element is created, the block size cannot be changed.

The following note may be of interest to users who must pay *very* close attention to performance issues: **VSsetblocksize** sets the block size only for blocks following the first block. The first block can be arbitrarily large; the library continues to write to it until it encounters an obstacle, at which point the linked block mechanism is invoked. For example, a Vdata A that is the last item in a file can continue to grow, simply extending the file. If a new Vdata B is then written, that new object is (normally) placed at the end of the file, blocking off extension of the prior Vdata, A. At this point, new writes to A will write data to linked blocks per the *block_size* and *num_blocks* settings.

FORTRAN integer function vsfsetblsz(vdata_id, block_size)

integer vdata_id, block_size

VSsetclass/vsfscls

int32 VSsetclass(int32 vdata_id, char *vdata_class)

vdata_id IN: Vdata identifier returned by **VSattach**

vdata_class IN: Name of the vdata class

Purpose Sets the class name of a vdata.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description VSsetclass sets the class name of the vdata identified by the parameter

vdata_id to the value of the parameter *vdata_class*.

At creation, the class name of a vdata is NULL. The class name may be reset more than once. Class names, like vdata names, can be any character string. They exist solely as meaningful labels to user applications and are not used by the HDF library in any way. Class names will be truncated to VSNAMELENMAX

(or 64) characters.

FORTRAN integer function vsfscls(vdata_id, vdata_class)

integer vdata_id

character*(*) vdata_class

VSsetexternalfile/vsfsextf

intn VSsetexternalfile(int32 vdata_id, char *filename, int32 offset)

vdata_id IN: Vdata identifier returned by **VSattach**

filename IN: Name of the external file

offset IN: Offset, in bytes, of the location in the external file the new data is to

be written

Purpose Stores vdata information in an external file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description VSsetexternalfile writes data in the vdata identified by the parameter *vdata_id*

in the file named *filename*, at the byte offset specified by the parameter offset.

Only the data will be stored externally. Attributes and all metadata will remain

in the primary HDF file.

IMPORTANT: The user must ensure that the external files are relocated along

with the primary file.

Read the Reference Manual page on SDsetexternalfile for more information

on using the external file feature.

FORTRAN integer function vsfsextf(vdata_id, filename, offset)

integer vdata_id, offset

character*(*) filename

VSsetfields/vsfsfld

intn VSsetfields(int32 vdata_id, char *field_name_list)

vdata_id IN: Vdata identifier returned by **VSattach**

field_name_list IN: List of the field names to be accessed

Purpose Specifies the fields to be accessed.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description VSsetfields specifies that the fields, whose names are listed in the parameter

field_name_list, of the vdata identified by the parameter *vdata_id* will be accessed by the next call to **VSread** or **VSwrite**. **VSsetfields** must be called

before any call to **VSread** or **VSwrite**.

For reading from a vdata, a call to **VSsetfields** sets up the fields that are to be retrieved from the records in the vdata. If the vdata is empty, **VSsetfields** will

return FAIL (or -1).

For writing to a vdata, **VSsetfields** can only be called once, to set up the fields in a vdata. Once the vdata fields are set, they may not be changed. Thus, to update some fields of a record after the first write, the user must read all the fields to a buffer, update the buffer, then write the entire record back to the vdata.

The parameter *field_name_list* is a character string that contains a commaseparated list of fieldnames (i.e., "PX,PY,PZ" in C and 'PX,PY,PZ' in Fortran). The combined width of the fields in a vdata must be less than MAX_FIELD_SIZE (or 65535) bytes. If an attempt to create a larger record is made, **VSsetfields** will return FAIL (or -1).

If the vdata is attached with an "r" access mode, the parameter *field_name_list* must contain only the fields that already exist in the vdata. If the vdata is attached with a "w" access mode, *field_name_list* can contain the names of any fields that have been defined by **VSfdefine** or any predefined fields.

FORTRAN integer function vsfsfld(vdata_id, field_name_list)

integer vdata_id

character*(*) field_name_list

VSsetinterlace/vsfsint

intn VSsetinterlace(int32 vdata_id, int32 interlace_mode)

vdata_id IN: Vdata identifier returned by **VSattach**

interlace_mode IN: Interlace mode of the data to be stored in the vdata

Purpose Sets the interlace mode of a vdata.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description VSsetinterlace sets the interlace mode of the vdata, *vdata_id*, to that specified by the parameter *interlace mode*. This routine can only be used when creating

new vdatas with write access.

The value of *interlace_mode* may be either full_interlace (or 0) or NO_INTERLACE (or 1). If this routine is not called, the default interlace mode of the vdata is full_interlace. The full_interlace option is more efficient than NO_INTERLACE although both require the same amount of disk space.

Specifying FULL_INTERLACE accesses the vdata by record; in other words, all values of all fields in a record are accessed before moving to the next record. Specifying No_INTERLACE accesses the vdata by field; in other words, all field values are accessed before moving to the next field. Thus, for writing data, all record data must be available before the write operation is invoked.

Note that the interlace mode of the data to be written is specified by a parameter of the **VSwrite** routine.

FORTRAN integer function vsfsint(vdata_id, interlace_mode)

integer vdata_id, interlace_mode

VSsetname/vsfsnam

int32 VSsetname(int32 vdata_id, char *vdata_name)

vdata_id IN: Vdata identifier returned by **VSattach**

vdata_name IN: Name of the vdata

Purpose Assigns a name to a vdata.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description VSsetname sets the name of the vdata identified by the parameter vdata_id to

the value of the parameter *vdata_name*.

At creation, the name of the vdata is NULL. The name may be reset more than once. Vdata names, like class names, can be any character string. They exist solely as a meaningful label for user applications and are not used by the HDF library in any way. Vdata names will be truncated to VSNAMELENMAX (or 64)

characters.

FORTRAN integer function vsfsnam(vdata_id, vdata_name)

integer vdata_id

character*(*) vdata_name

VSsetnumblocks/vsfsetnmbl

intn VSsetnumblocks(int32 vdata_id, int32 num_blocks)

vdata id IN: Vdata identifier

num_blocks IN: Number of blocks to be used for the linked-block element

Purpose Sets the number of blocks for a linked-block Vdata element.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description VSsetnumblocks sets the number of blocks in linked-block elements that will

be used to store Vdatas.

The default number of blocks is <code>HDF_APPENDABLE_BLOCK_NUM</code>, which is set to 16 in the library as it is distributed. **VSsetnumblocks** modifies that default value and must be called before the first write to the Vdata. Once the linked-

block element is created, the number of blocks cannot be changed.

FORTRAN integer function vsfsetnmbl(vdata_id, num_blocks)

integer vdata_id, num_blocks

VSsizeof/vsfsiz

int32 VSsizeof(int32 vdata_id, char *field_name_list)

vdata_id IN: Vdata identifier returned by **VSattach**

field_name_list IN: Name(s) of the fields to check

Purpose Computes the size, in bytes, of the given field(s) for the local machine.

Return value Returns the fields size if successful and FAIL (or -1) otherwise.

Description VSsizeof computes the size, in bytes, of the fields specified in the parameter

field_name_list in the vdata identified by the parameter *vdata_id*.

The parameter *field_name_list* specifies a single field or several commaseparated fields. The field or fields should already exist in the vdata. If more than one field is specified, **VSsizeof** will return the total sizes of all of the

fields.

FORTRAN integer function vsfsiz(vdata_id, field_name_list)

integer vdata_id

character*(*) field_name_list

VSwrite/vsfwrt/vsfwrtc/vsfwrit

int32 VSwrite(int32 *vdata_id*, uint8 **databuf*, int32 *n_records*, int32 *interlace_mode*)

vdata id IN: Vdata identifier returned by **VSattach**

databuf IN: Buffer of records to be written to the vdata

 $n_{records}$ IN: Number of records to be written

interlace_mode IN: Interlace mode of the buffer in memory

Purpose Writes data to a vdata.

Return value Returns the total number of records written if successful and FAIL (or -1)

otherwise.

VSwrite writes the data stored in the buffer *databuf* into the vdata identified by the parameter *vdata_id*. The parameter *n_records* specifies the number of records to be written. The parameter *interlace mode* defines the interlace

mode of the vdata fields stored in the buffer databuf.

Valid values for *interlace_mode* are FULL_INTERLACE (or 0) and No_INTERLACE (or 1). Selecting FULL_INTERLACE fills *databuf* by record and is recommended for speed and efficiency. Specifying No_INTERLACE causes *databuf* to be filled by field, i.e., all values of a field in all records must be written before moving to the next field. Thus, all data must be available before writing. If the data is to be written to the vdata with an interlace mode different from that of the buffer, **VSsetinterlace** must be called prior to **VSwrite**. Note that the default interlace mode of a vdata is FULL_INTERLACE.

It is assumed that the data in *databuf* is organized as specified by the parameter *interlace_mode*. The number and order of the fields organized in the buffer must correspond with the number and order of the fields specified in the call to **VSsetfields**, which finalizes the vdata fields definition. Since **VSwrite** writes the data in *databuf* contiguously to the vdata, **VSfpack** must be used to remove any "padding", or non-data spaces, used for vdata field alignment. This process is called packing. Refer to the discussion of **VSfpack** in the HDF User's Guide for more information.

Before writing data to a newly-created vdata, **VSdefine** and **VSsetfields** must be called to define the fields to be written.

Note that there are three FORTRAN-77 versions of this routine: **vsfwrt** is for buffered numeric data, **vsfwrtc** is for buffered character data and **vsfwrit** is for generic packed data.

FORTRAN integer function vsfwrt(vdata_id, databuf, n_records, interlace_mode)

integer vdata_id, n_records, interlace_mode

<valid numeric data type> databuf(*)

DF24addimage/d2aimg

intn DF24addimage(char *filename, VOIDP image, int32 width, int32 height)

filename IN: Name of the file

image IN: Pointer to the image array

width IN: Number of columns in the image

height IN Number of rows in the image

Purpose Writes a 24-bit image to the specified file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description DF24addimage appends a 24-bit raster image set to the file. Array *image* is assumed to be width *x* height *x* 3 bytes. In FORTRAN-77, the dimensions of

the array *image* must be the same as the dimensions of the image data.

The order in which dimensions are declared is different between C and FORTRAN-77. Ordering varies because FORTRAN-77 arrays are stored in column-major order, while C arrays are stored in row-major order. (Row-major)

order implies that the last coordinate varies fastest).

When **DF24addimage** writes an image to a file, it assumes row-major order. The FORTRAN-77 declaration that causes an image to be stored in this way must have the width as its first dimension and the height as its second

dimension. In other words, the image must be built "on its side".

FORTRAN integer function d2aimg(filename, image, width, height)

character*(*) filename

<valid numeric data type> image

integer width, height

DF24getdims/d2gdims

intn DF24getdims (char *filename, int32 *width, int32 *height, intn *interlace_mode)

filename IN: Name of the file

width OUT: Width of the image

height OUT: Height of the image

interlace_mode OUT: File interlace mode of the image

Purpose Retrieves dimensions and interlace storage scheme of next image.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description DF24getdims retrieves the dimensions and interlace of the image. If the file is

being opened for the first time, **DF24getdims** returns information about the first image in the file. If an image has already been read, **DF24getdims** finds the next image. In this way, images are read in the same order in which they

were written to the file.

If the dimensions and interlace of the image are known beforehand, there is no need to call **DF24getdims**. Simply allocate arrays with the proper dimensions for the image and invoke **DF24getimage** to read the images. If, however, you do not know the values of width and height, you must call **DF24getdims** to get them and then use them to determine the amount of memory to allocate for the image buffer.

Successive calls to **DF24getdims** and **DF24getimage** retrieve all of the images in the file in the sequence in which they were written.

The interlace mode codes are: 0 for pixel interlacing, 1 for scan-line interlacing

and 2 for scan-plane interlacing.

FORTRAN integer function d2gdims(filename, width, height, interlace_mode)

character*(*) filename

integer width, height, interlace_mode

DF24getimage/d2gimg

intn DF24getimage(char *filename, VOIDP image, int32 width, int32 height)

filename IN: Name of the HDF file

image OUT: Pointer to image buffer

width IN: Number of columns in the image

height IN: Number of rows in the image

Purpose Retrieves an image from the next 24-bit raster image set.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description DF24getimage retrieves the image and stores it in an array. If **DF24getdims**

has not been called, DF24getimage finds the next image in the same way that

DF24getdims does.

The amount of space allocated for the image should be width *x* height *x* 3

bytes.

To specify that the next call to **DF24getimage** should read the raster image using an interlace other than the interlace used to store the image in the file,

first call **DF24reqil**.

FORTRAN integer function d2gimg(filename, image, width, height)

character*(*) filename, image

integer width, height

DF24lastref/d2lref

uint16 DF24lastref()

Purpose Retrieves the last reference number written to or read from a 24-bit raster

image set.

Return value Returns the non-zero reference number if successful and FAIL (or -1)

otherwise.

Description This routine is primarily used for attaching annotations to 24-bit images and

adding 24-bit images to vgroups. DF24lastref returns the reference number of

the last 24-bit raster image read or written.

FORTRAN integer function d2lref()

DF24nimages/d2nimg

intn DF24nimages(char *filename)

filename IN: Name of the file

Purpose Counts the number of 24-bit raster images contained in an HDF file.

Return value Returns the number of 24-bit images in the file if successful and FAIL (or -1)

otherwise.

Description DF24nimages counts the number of 24-bit images stored in the file.

FORTRAN integer function d2nimg(filename)

character*(*) filename

DF24putimage/d2pimg

intn DF24putimage(char *filename, VOIDP image, int32 width, int32 height)

filename IN: Name of the file

image IN: Pointer to the image array

width IN: Number of columns in the image

height IN: Number of rows in the image

Purpose Writes a 24-bit image as the first image in the file.

Return value Returns Successful and FAIL (or -1) otherwise.

Description The array image is assumed to be width x height x 3 bytes. **DF24putimage**

overwrites any information that exists in the HDF file. To append a new image

to a file instead of overwriting an existing file, use **DF24addimage**.

FORTRAN integer function d2pimg(filename, image, width, height)

character*(*) filename

<valid numeric data type> image

integer width, height

DF24readref/d2rref

intn DF24readref(char *filename, uint16 ref)

filename IN: Name of the file

ref IN: Reference number for the next call to **DF24getimage**

Purpose Specifies the reference number of the next image to be read when

DF24getimage is next called.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description DF24readref is commonly used in conjunction with **DFANlablist**, which

returns a list of labels for a given tag together with their reference numbers. It provides a means of non-sequentially accessing 24-bit raster images in a file.

There is no guarantee that reference numbers appear in sequence in an HDF file. Therefore, it is not safe to assume that a reference number is the index of

an image.

FORTRAN integer function d2rref(filename, ref)

character*(*) filename

integer ref

DF24reqil/d2reqil

intn DF24reqil (intn il)

il IN Memory interlace of the next image read

Purpose Specifies the interlace mode for the next call to **DF24getimage** will use.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description Regardless of what interlace scheme is used to store the image, **DF24reqil**

causes the image to be loaded into memory and be interlaced according to the

specification of il.

Because a call to **DF24reqil** may require a substantial reordering of the data, slower I/O performance could result than would be achieved if no change in

interlace were requested.

The interlace mode codes are: 0 for pixel interlacing,1 for scan-line interlacing

and 2 for scan-plane interlacing.

FORTRAN integer function d2reqil(i1)

integer il

DF24restart/d2first

intn DF24restart()

Purpose Specifies that the next 24-bit image read from the file will be the first one

rather than the 24-bit image following the one most recently read.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

FORTRAN integer function d2first()

DF24setcompress/d2scomp

intn DF24setcompress(int32 type, comp_info *cinfo)

type IN: Type of compression

cinfo IN: Pointer to compression information structure

Purpose

Set the type of compression to use when writing the next 24-bit raster image.

Return value

Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description

This routines provides a method for compressing the next raster image written. The type can be one of the following values: COMP_NONE, COMP_JPEG, COMP_RLE, COMP_IMCOMP, COMP_NONE is the default for storing images if this routine is not called, therefore images are not compressed by default. COMP_JPEG compresses images with a JPEG algorithm, which is a lossy method. COMP_RLE uses lossless run-length encoding to store the image. COMP_IMCOMP uses a lossy compression algorithm called IMCOMP, and is included for backward compatibility only.

The comp_info union contains algorithm-specific information for the library routines that perform the compression and is defined in the hcomp.h header file as follows:

```
typedef union tag_comp_info
   struct
   {
       intn quality;
       intn force_baseline;
   } jpeg;
   struct
       int32 nt;
       intn sign ext;
       intn fill one;
       intn start_bit;
       intn bit len;
   } nbit;
   struct
       intn
              skp_size;
   } skphuff;
   struct
              level;
       intn
   } deflate;
comp_info
```

This union is defined to provide future expansion, but is currently only used by the COMP_JPEG compression type. A pointer to a valid COMP_info union is required for all compression types other than COMP_JPEG, but the values in the union are not used. The COMP_info union is declared in the header file hdf.h and is shown here for informative purposes only, it should not be re-declared in a user program.

For COMP_JPEG compression, the quality member of the jpeg structure must be set to the quality of the stored image. This number can vary from 100, the best quality, to 0, terrible quality. All images stored with COMP_JPEG compression are stored in a lossy manner, even images stored with a quality of 100. The ratio of size to perceived image quality varies from image to image, some experimentation may be required to determine an acceptable quality factor for a given application. The force_baseline parameter determines whether the quantization tables used during compression are forced to the range 0-255. The force_baseline parameter should normally be set to 1 (forcing baseline results), unless special applications require non-baseline images to be used.

If the compression type is JPEG, **d2scomp** defines the default JPEG compression parameters to be used. If these parameters must be changed later, the **d2sjpeg** routine must be used. (See the Reference Manual entry for **d2sjpeg**)

FORTRAN

integer function d2scomp(type)

integer type

d2scomp

integer d2scomp(integer quality, integer baseline)

quality IN: JPEG quality specification

baseline IN: JPEG baseline specification

Purpose Fortran-specific routine that sets the parameters needed for the JPEG

algorithm.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description d8sjpeg changes the JPEG compression parameter settings set in the d8scomp

routine.

HDF Reference Manual d2sjpeg

d2sjpeg

integer d2sjpeg(integer quality, integer baseline)

quality IN: JPEG quality specificationbaseline IN: JPEG baseline specification

Purpose Fortran-specific routine that sets the parameters needed for the JPEG

algorithm.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description d2sjpeg changes the JPEG compression parameter settings set in the d2scomp

routine.

DF24setdims/d2sdims

intn DF24setdims(int32 width, int32 height)

width IN: Number of columns in the image

height IN: Number or rows in the image

Purpose Set the dimensions of the next image to be written to a file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

FORTRAN integer function d2sdims(width, height)

integer width, height

DF24setil/d2setil

intn DF24setil(intn il)

il IN: Interlace mode

Purpose Specifies the interlace mode to be used on subsequent writes.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description DF24setil sets the interlace mode to be used when writing out the raster image

set for a 24-bit image by determining the interlace mode of the image data in memory. If **DF24setil** is not called, the interlace mode is assumed to be 0.

The interlace mode codes are: 0 for pixel interlacing, 1 for scan-line

interlacing and 2 for scan-plane interlacing.

FORTRAN integer function d2setil(i1)

integer il

DFR8addimage/d8aimg

intn DFR8addimage(char *filename, VOIDP image, int32 width, int32 height, uint16 compress)

filename IN: Name of the file

image IN: Array containing the image data

width IN: Number of columns in the image

height IN: Number of rows in the image

compress IN: Type of compression to use, if any

Purpose Appends the RIS8 for the image to the file.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description DFR8addimage is functionally equivalent to **DFR8putimage**, except that

DFR8putimage cannot append image data; it only overwrites.

FORTRAN integer function d8aimg(filename, image, width, height, compress)

character*(*) filename, image

integer width, height

integer compress

DFR8getdims/d8gdims

intn DFR8getdims(char *filename, int32 *width, int32 *height, intn *ispalette)

filename IN: Name of the HDF file

width OUT: Number of columns in the next image in the file

height OUT: Number of rows in the next image in the file

ispalette OUT: Indicator of the existence of a palette

Purpose Opens the file, finds the next image, retrieves the dimensions of the image, and

determines whether there is a palette associated with the image.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description DFR8getdims retrieves the dimensions of the image and indicates whether a

palette is associated and stored with the image. If the file is being opened for the first time, **DFR8getdims** returns information about the first image in the file. If an image has already been read, **DFR8getdims** finds the next image. Thus, images are read in the same order in which they were written to the file.

Normally, **DFR8getdims** is called before **DFR8getimage** so that if necessary, space allocations for the image and palette can be checked, and the dimensions can be verified. If this information is already known, **DFR8getdims** need not

be called.

Valid values of ispalette are: 1 if there is a palette, or 0 if not.

FORTRAN integer function d8gdims(filename, width, height, ispalette)

character*(*) filename

integer width, height

integer ispalette

DFR8getimage/d8gimg

intn DFR8getimage(char *filename, uint8 *image, int32 width, int32 height, uint8 *palette)

IN: Name of the file filename

OUT: Buffer for the returned image image

width IN: Width of the image data buffer

height IN: Height of the image data buffer

palette OUT: Palette data

Purpose To retrieve the image and its palette, if it is present, and store them in the

specified arrays.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description In C, if *palette* is NULL, no palette is loaded, even if one is stored with the

image. In FORTRAN-77, an array must be allocated to store the palette, even if no palette is expected to be stored. If the image in the file is compressed, **DFR8getimage** automatically decompresses it. If **DFR8getdims** has not been

called, **DFR8getimage** finds the next image in the same way that

DFR8getdims does.

The *width* and *height* parameters specify the number of columns and rows, respectively, in the array which you've allocated in memory to store the image.

The image may be smaller than the allocated space.

The order in which you declare dimensions is different between C and FORTRAN-77. Ordering varies because FORTRAN-77 arrays are stored in column-major order, while C arrays are stored in row-major order. (Row-major order implies that the horizontal coordinate varies fastest). When **d8gimg** reads an image from a file, it assumes row-major order. The FORTRAN-77 declaration that causes an image to be stored in this way must have the width as its first dimension and the height as its second dimension. To take this into account as you read image in your program, the image must be built "on its

side".

FORTRAN integer function d8gimg(filename, image, width, height, palette)

character*(*) filename, image, palette

integer width, height

DFR8getpalref

intn DFR8getpalref(uint16 *pal_ref)

pal_ref OUT: Reference number of the palette

Purpose Retrieves the reference number of the palette associated with the last image

accessed.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description Make certain that **DFR8getdims** is called before **DFR8getpalref**.

DFR8lastref/d8lref

uint16 DFR8lastref()

Purpose Retrieves the last reference number written to or read from an RIS8.

Return value Returns a non-zero reference number if successful and FAIL (or 0) otherwise.

Description This routine is primarily used for attaching annotations to images and adding

images to vgroups. DFR8lastref returns the reference number of last raster

image set read or written.

FORTRAN integer function d8lref()

DFR8nimages/d8nims

intn DFR8nimages(char *filename)

filename IN: Name of the HDF file

Purpose Retrieves the number of 8-bit raster images stored in the specified file.

Return value Returns the number of raster images in the file if successful and FAIL (or -1)

otherwise.

FORTRAN integer function d8nims(filename)

character*(*) filename

DFR8putimage/d8pimg

intn DFR8putimage(char *filename, VOIDP image, int32 width, int32 height, uint16 compress)

filename IN: Name of the file to store the raster image in

image IN: Array with image to put in file

width IN: Number of columns in the image

height IN: Number of rows in the image

compress IN: Type of compression used, if any

Purpose Writes the RIS8 for the image as the first image in the file, overwriting any

information previously in the file.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description The *compress* parameter identifies the method to be used for compressing the

data, if any. If IMCOMP compression is used, the image must include a

palette.

DFR8putimage overwrites any information that exists in the HDF file. To write an image to a file by appending it, rather than overwriting it, use

DFR8addimage.

In FORTRAN-77, the dimensions of the *image* array must be the same as the dimensions of the image itself.

The order in which dimensions are declared is different between C and FORTRAN-77. Ordering varies because FORTRAN-77 arrays are stored in column-major order, while C arrays are stored in row-major order. (Row-major order insplies that the horizontal coordinate varies feetest). When

order implies that the horizontal coordinate varies fastest). When **DFR8** nutimage writes an image to a file, it assumes row-major of

DFR8putimage writes an image to a file, it assumes row-major order. The FORTRAN-77 declaration that causes an image to be stored in this way must have the width as its first dimension and the height as its second dimension, the reverse of the way it is done in C. To take this into account as you build your image in your FORTRAN-77 program, the image must be built "on its side".

FORTRAN integer function d8pimg(filename, image, width, height, compress)

character*(*) filename, image

integer width, height, compress

DFR8readref/d8rref

intn DFR8readref(char *filename, uint16 ref)

filename IN: Name of the file

ref IN: Reference number for next **DFR8getimage**

Purpose Specifies the reference number of the image to be read when **DFR8getimage**

is next called.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description DFR8readref is usually used in conjunction with **DFANlablist**, which returns

a list of labels for a given tag together with their reference numbers. It provides, in a sense, a random access to images. There is no guarantee that reference numbers appear in sequence in an HDF file; therefore, it is not safe to

assume that a reference number is the index of an image.

FORTRAN integer function d8rref(filename, ref)

character*(*) filename

integer ref

DFR8restart/d8first

intn DFR8restart()

Purpose Causes the next get command to read from the first raster image set in the file.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

FORTRAN integer function d8first()

DFR8setcompress/d8scomp

intn DFR8setcompress(int32 type, comp_info *cinfo)

type IN: Type of compression

cinfo IN: Pointer to compression information structure

Purpose

Sets the compression type to be used when writing the next 8-bit raster image.

Return value

Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description

This routine provides a method for compressing the next raster image written. The type can be one of the following values: COMP_NONE, COMP_JPEG, COMP_RLE, COMP_IMCOMP. COMP_NONE is the default for storing images if this routine is not called, therefore images are not compressed by default. COMP_JPEG compresses images with a JPEG algorithm, which is a lossy method. COMP_RLE uses lossless run-length encoding to store the image. COMP_IMCOMP uses a lossy compression algorithm called IMCOMP, and is included for backward compatibility only.

The comp_info union contains algorithm-specific information for the library routines that perform the compression and is defined in the hcomp.h header file as follows (refer to the header file for inline documentation):

```
typedef union tag_comp_info
   struct
   {
       intn quality;
             force baseline;
       intn
   } jpeg;
   struct
       int32 nt;
       intn sign ext;
       intn fill one;
       intn start_bit;
       intn bit len;
   } nbit;
   struct
       intn
              skp_size;
   } skphuff;
   struct
              level;
       intn
   } deflate;
comp_info;
```

This union is defined to provide future expansion, but is currently only used by the COMP_JPEG compression type. A pointer to a valid comp_info union is required for all compression types other than COMP_JPEG, but the values in the union are not used. The comp_info union is declared in the header file hdf.h and is shown here for informative purposes only, it should not be re-declared in a user program.

For COMP_JPEG compression, the quality member of the jpeg structure must be set to the quality of the stored image. This number can vary from 100, the best quality, to 0, terrible quality. All images stored with COMP_JPEG compression are stored in a lossy manner, even images stored with a quality of 100. The ratio of size to perceived image quality varies from image to image, some experimentation may be required to determine an acceptable quality factor for a given application. The force_baseline parameter determines whether the quantization tables used during compression are forced to the range 0-255. It should normally be set to 1 (forcing baseline results), unless special applications require non-baseline images to be used.

If the compression type is JPEG, **d8scomp** defines the default JPEG compression parameters to be used. If these parameters must be changed later, the **d8sjpeg** routine must be used. (Refer to the Reference Manual page on **d8sjpeg**).

FORTRAN integer function d8scomp(type)

integer type

d8scomp

integer d8scomp(integer quality, integer baseline)

quality IN: JPEG quality specification

baseline IN: JPEG baseline specification

Purpose Fortran-specific routine that sets the parameters needed for the JPEG

algorithm.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description d8sjpeg changes the JPEG compression parameter settings set in the d8scomp

routine.

HDF Reference Manual d8sjpeg

d8sjpeg

integer d8sjpeg(integer quality, integer baseline)

quality IN: JPEG quality specificationbaseline IN: JPEG baseline specification

Purpose Fortran-specific routine that sets the parameters needed for the JPEG

algorithm.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description d8sjpeg changes the JPEG compression parameter settings set in the d8scomp

routine.

DFR8setpalette/d8spal

intn DFR8setpalette(uint8 *palette)

palette IN: Palette data

Purpose Indicate which palette, if any, is to be used for subsequent image sets.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description The specified palette remains the default palette until changed by a subsequent

call to **DFR8setpalette**.

FORTRAN integer function d8spal(palette)

character*(*) palette

DFR8writeref/d8wref

intn DFR8writeref(char *filename, uint16 ref)

filename IN: Name of the HDF file

ref IN: Reference number for next call to **DFR8putimage** or

DFR8addimage

Purpose Specifies the reference number of the image to be written when

DFR8addimage or **DFR8putimage** is next called.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description It is unlikely that you will need this routine, but if you do, use it with caution.

There is no guarantee that reference numbers appear in sequence in an HDF file; therefore, it is not safe to assume that a reference number is the index of an image. In addition, using an existing reference number will overwrite the

existing 8-bit raster image data.

FORTRAN integer function d8wref(filename, ref)

character*(*) filename

integer ref

DFPaddpal/dpapal

intn DFPaddpal(char *filename, VOIDP palette)

filename IN: Name of the HDF file

palette IN: Buffer containing the palette to be written

Purpose Appends a palette to a file.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description If the named file does not exist, it is created and the palette written to it. The

palette buffer should beat least 768 bytes in length.

FORTRAN integer function dpapal(filename, palette)

character*(*) filename, palette

DFPgetpal/dpgpal

intn DFPgetpal(char *filename, VOIDP palette)

filename IN: Name of the HDF file

palette OUT: Buffer for the returned palette

Purpose Retrieves the next palette from file and stores it in the buffer *palette*.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description The *palette* buffer is assumed to be at least 768 bytes long. Successive calls to

DFPgetpal retrieve the palettes in the sequence they are stored in the file.

FORTRAN integer function dpgpal(filename, palette)

character*(*) filename. palette

DFPlastref/dplref

uint16 DFPlastref(void)

Purpose Returns the value of the reference number most recently read or written by a

palette function call.

Return value Returns the reference number if successful and FAIL (or -1) otherwise.

FORTRAN integer function dplref()

DFPnpals/dpnpals

intn DFPnpals(char *filename)

filename IN: Name of the file

Purpose Indicates the number of palettes in the specified file.

Return value Returns the number of palettes if successful and FAIL (or -1) otherwise.

FORTRAN integer function dpnpals(filename)

character*(*) filename

DFPputpal/dpppal

intn DFPputpal (char *filename, VOIDP palette, intn overwrite, char *filemode)

filename IN: Name of the file

palette IN: Buffer containing the palette to be written

IN: Flag identifying the palette to be written overwrite

filemode IN: File access mode

Purpose Writes a palette to the file.

Returns Succeed (or 0) if successful and FAIL (or -1) otherwise. Return value

Description This routine provides more control of palette write operations than

DFPaddpal. Note that the combination *filemode=*"w" and *overwrite=*1 has no meaning and will result in an error condition. To overwrite a palette, *filename* must be the same filename as the last file accessed through the DFP interface.

Valid values for *overwrite* are: 1 to overwrite last palette; 0 to write a new

palette.

Valid values for *filemode* are: "a" to append the palette to the file and "w" to

create a new file.

The *palette* buffer must be at least 768 bytes in length.

FORTRAN integer function dpppal(filename, palette, overwrite, filemode)

character*(*) filename, palette, filemode

integer overwrite

DFPreadref/dprref

intn DFPreadref(char *filename, uint16 ref)

filename IN: Name of the file

ref IN: Reference number to be used in next **DFPgetpal** call

Purpose Retrieves the reference number of the palette to be retrieved next by

DFPgetpal.

Return value Returns SUCCEED (or 0) if the palette with the specified reference number exists

and FAIL (or -1) otherwise.

Description Used to set the reference number of the next palette to be retrieved.

FORTRAN integer function dprref(filename, ref)

character*(*) filename

integer ref

DFPrestart/dprest

intn DFPrestart()

Purpose Specifies that DFPgetpal will read the first palette in the file, rather than the

next unread palette.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

FORTRAN integer function dprest()

DFPwriteref/dpwref

intn DFPwriteref(char *filename, uint16 ref)

filename IN: Name of the file

ref IN: Reference number to be assigned to the next palette written to a file

Purpose Determines the reference number of the next palette to be written.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description The file name is ignored. The next palette written, regardless of the filename, is

assigned the reference number ref.

FORTRAN integer function dpwref(filename, ref)

character*(*) filename

integer ref

HDF Reference Manual DFKNTsize

DFKNTsize

int DFKNTsize(int32 data_type)

data_type IN: Data type

Purpose Determines the size of the specified data type.

Return value Returns the size, in bytes, of the specified data type if successful and FAIL (or -

1) otherwise.

DFUfptoimage/duf2im

Description

int DFUfptoimage(int32 hdim, int32 vdim, float32 max, float32 min, float32 *hscale, float32 *vscale, float32 *data, uint8 *palette, char *outfile, int ct_method, int32 hres, int32 vres, int compress)

hdim	IN:	Horizontal dimension of the input data	
vdim	IN:	Vertical dimension of the input data	
max	IN:	Maximum value of the input data	
min	IN:	Minimum value of the input data	
hscale	IN:	Horizontal scale of the input data (optional)	
vscale	IN:	Vertical scale of the input data (optional)	
data	IN:	Buffer containing the input data	
palette	IN:	Pointer to the palette data	
outfile	IN:	Name of the file the image data will be stored in	
ct_method	IN:	Color transformation method	
hres	IN:	Horizontal resolution to be applied to the output image	
vres	IN:	Vertical resolution to be applied to the output image	
compress	IN:	Compression flag	

Purpose Converts floating point data to 8-bit raster image format and stores the converted image data in the specified file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

This routine is very similar to the utility fptohdf, which takes its input from one or more files, rather than from internal memory. Another difference is that this routine allows compression (run-length encoding), whereas fptohdf does not at present.

As this routine is meant to mimic many of the features of NCSA DataScope, much of the code has been taken directly from the DataScope source.

Valid values for *ct_method* are: 1 (or EXPAND) for expansion and 2 (or INTERP) for interpolation.

Valid values for *compress* are: 0 for no compression and 1 for compression enabled.

FORTRAN integer function duf2im(hdim, vdim, max, min, hscale, vscale, data, palette, outfile, ct_method, hres, vres, compress)

integer hdim, vdim

real max, min, hscale, vscale, data
character*(*) palette, outfile
integer ctmethod, hres, vres, compress

DFANaddfds/daafds

intn DFANaddfds(int32 file_id, char *description, int32 desc_len)

file_id IN: File identifier returned by **Hopen**

description IN: Sequence of ASCII characters (may include NULL or '\0')

desc_len IN: Length of the description

Purpose Adds a file description to a file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description These annotations are associated with the file, not with any particular object

within the file. The parameter description can contain any sequence of ASCII characters. It does not have to be a string. Use the general purpose routines **Hopen** and **Hclose** to manage file access as the file annotation routines will not

open and close HDF files.

FORTRAN integer function daafds(file_id, description, desc_len)

integer file_id, desc_len
character*(*) description

DFANaddfid/daafid

intn DFANaddfid(int32 file_id, char *label)

file_id IN: The file identifier returned by **Hopen**.

label IN: A null-terminated string.

Purpose Writes a file label to a file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description These annotations are associated with the file, not with any particular object

within the file. The label must be a single string. Use the general purpose routines **Hopen** and **Hclose** to manage file access because the file annotation

routines will not open and close HDF files for you.

In the FORTRAN-77 version, the string length for the label should be close to the actual expected string length, because in FORTRAN-77 string lengths generally are assumed to be the declared length of the array that holds the

string.

FORTRAN integer function daafid(file_id, label)

integer file_id

character*(*) label

DFANclear/daclear

intn DFANclear()

Purpose Resets all internal library structures and parameters of the DFAN annotation

interface.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description When a file is regenerated in a single run by a library routine of another

interface (such as DFSDputdata), DFANclear should be called to reset the

interface.

FORTRAN integer function daclear()

DFANgetdesc/dagdesc

intn DFANgetdesc(char *filename, uint16 tag, uint16 ref, char *desc_buf, int32 buf_len)

filename IN: Name of the file

tag IN: Tag of the data object assigned the description

ref IN: Reference number of the data object assigned the description

desc_buf OUT: Buffer allocated to hold the description

buf_len IN: Size of the buffer allocated to hold the description

Purpose Reads the description assigned to the data object with the given tag and

reference number.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description The parameter *buf_len* specifies the storage space available for the description.

The length of buf_len must account for the null termination character appended

to the description.

FORTRAN integer function dagdesc(filename, tag, ref, desc_buf, buf_len)

character*(*) filename, desc_buf

integer tag, ref
integer buf_len

DFANgetdesclen/dagdlen

int32 DFANgetdesclen(char *filename, uint16 tag, uint16 ref)

filename IN: Name of the file

tag IN: Tag of the data object assigned the description

ref IN: Reference number of the data object assigned the description

Purpose Retrieves the length of a description of the data object with the given tag and

reference number.

Return value Returns the length of a description if successful and FAIL (or -1) otherwise.

Description This routine should be used to insure that there is enough space allocated for a

description before actually reading it.

FORTRAN integer function dagdlen(filename, tag, ref)

character*(*) filename

integer tag, ref

DFANgetfds/dagfds

int32 DFANgetfds(int32 file_id, char *desc_buf, int32 buf_len, intn isfirst)

file_id IN: File identifier returned by **Hopen**

desc_buf OUT: The buffer allocated to hold the description

buf_len IN: Size of the buffer allocated to hold the description

isfirst IN: Determines the description to be retrieved

Purpose Reads the next file description.

Return value Returns the length of the file description if successful and FAIL (or -1)

otherwise.

Description If *isfirst* is 0, **DFANgetfds** gets the next file description from an HDF file. For

example, if there are three file descriptions in a file, three successive calls to **DFANgetfds** will get all three descriptions. If *isfirst* is 1, **DFANgetfds** gets the

first file description.

Valid values for isfirst are: 1 to read the first description and 0 to read the next

description.

FORTRAN integer function dagfds(file_id, desc_buf, buf_len, isfirst)

integer file_id, buf_len, isfirst

character*(*) desc_buf

DFANgetfdslen/dagfdsl

int32 DFANgetfdslen(int32 file_id, intn isfirst)

file_id IN: File identifier returned by **Hopen**

isfirst IN: Determines the description the retrieved length information applies

to

Purpose Returns the length of a file description.

Return value Returns the length of the file description if successful and FAIL (or -1)

otherwise.

Description When **DFANgetfdslen** is first called for a given file, it returns the length of the

first file description. In order to get the lengths of successive file descriptions, you must call **DFANgetfds** between calls to **DFANgetfdslen**. Successive calls to **DFANgetfdslen** without calling **DFANgetfds** between them will return the

length of the same file description.

Valid values for isfirst are: 1 to read the length of the first description and 0 to

read the length of the next description.

FORTRAN integer function dagfdsl(file_id, isfirst)

integer file_id, isfirst

DFANgetfid/dagfid

int32 DFANgetfid(int32 file_id, char *desc_buf, int32 buf_len, intn isfirst)

file_id IN: File identifier returned by **Hopen**

label_buf OUT: The buffer allocated to hold the label

buf_len IN: Size of the buffer allocated to hold the label

isfirst IN: Determines the file label to be retrieved

Purpose Reads a file label from a file.

Return value Returns the length of the file description if successful and FAIL (or -1)

otherwise.

Description If *isfirst* is 0, **DFANgetfid** gets the next file label from the file. If *isfirst* is 1,

DFANgetfid gets the first file label in the file. If *buf_len* is not large enough,

the label is truncated to *buf_len-1* characters in the buffer *label_buf*.

Valid values of isfirst are: 1 to read the first label, 0 to read the next label

FORTRAN integer function dagfid(file_id, label_buf, buf_len, isfirst)

integer file_id, buf_len, isfirst

character*(*) label_buf

DFANgetfidlen/dagfidl

int32 DFANgetfidlen(int32 file_id, intn isfirst)

file_id IN: File identifier returned by **Hopen**

isfirst IN: Determines the file label the retrieved length information applies to

Purpose Returns the length of a file label.

Return value Returns the length of the file label if successful and FAIL (or -1) otherwise.

Description When **DFANgetfidlen** is first called for a given file, it returns the length of the

first file label. In order to retrieve the lengths of successive file labels, **DFANgetfid** must be called between calls to **DFANgetfidlen**. Otherwise, successive calls to **DFANgetfidlen** will return the length of the same file label.

Valid values of *isfirst* are: 1 to read the first label, and 0 to read the next label.

FORTRAN integer function dagfidl(file_id, isfirst)

integer file_id, isfirst

DFANgetlabel/daglab

intn DFANgetlabel(char *filename, uint16 tag, uint16 ref, char *label_buf, int32 buf_len)

filename IN: Name of the HDF file

tag IN: Tag of the data object assigned the label

ref IN: Reference number of the data object assigned the label

label buf OUT: Buffer for the label

buf_len IN: Size of the buffer allocated for the label

Purpose Reads the label assigned to the data object identified by the given tag and

reference number.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description The parameter *buf_len* specifies the storage space available for the label. The

length of buf_len must account for the null termination character appended to

the annotation.

FORTRAN integer function daglab(filename, tag, ref, label_buf, buf_len)

character*(*) filename, label_buf

integer tag, ref, buf len

DFANgetlablen/dagllen

int32 DFANgetlablen(char *filename, uint16 tag, uint16 ref)

filename IN: Name of the file

tag IN: Tag of the data object assigned the label

ref IN: Reference number the data object assigned the label

Purpose Returns the length of a label assigned to the object with a given tag and

reference number.

Return value Returns the length of the label if successful and FAIL (or -1) otherwise.

Description This routine should be used to insure that there is enough space allocated for a

label before actually reading it.

FORTRAN integer function dagllen(filename, tag, ref)

character*(*) filename

integer tag, ref

DFANlablist/dallist

int DFANlablist(char *filename, uint16 tag, unit16 ref_list[], char *label_list, int list_len, intn *label_len*, intn *start_pos*)

filename	IN:	Name of the file
tag	IN:	Tag to be queried
ref_list	OUT:	Buffer for the returned reference numbers
label_list	OUT:	Buffer for the returned labels
list_len	IN:	Size of the reference number list and the label list
label_len	IN:	Maximum length allowed for a label
start_pos	IN:	Starting position of the search
Purpose	Returns tag.	a list of all reference numbers and labels (if labels exist) for a given
	-	

Return value Returns the number of reference numbers found if successful and FAIL (or -1)

otherwise.

Description Entries are returned from the *start_pos* entry up to the *list_len* entry.

> The *list_len* determines the number of available entries in the reference number and label lists, *label len* is the maximum length allowed for a label, and start_pos tells which label to start reading for the given tag. (If start_pos is 1, for instance, all labels will be read; if *start_pos* is 4, all but the first 3 labels will be read.) The *ref* list contains a list of reference numbers for all objects with a given tag. The *label_list* contains a corresponding list of labels, if any. If there is no label stored for a given object, the corresponding entry in *label_list* is an empty string.

> Taken together, the ref_list and label_list constitute a directory of all objects and their labels (where they exist) for a given tag. The *label_list* parameter can display all of the labels for a given tag. Or it can be searched to find the reference number of a data object with a certain label. Once the reference number for a given label is found, the corresponding data object can be accessed by invoking other HDF routines. Therefore, this routine provides a mechanism for the direct access to data objects in HDF files.

```
FORTRAN
               integer function dallist(filename, tag, ref_list, label_list,
                                 list_len, label_len, start_pos)
               character*(*) filename, label list
               integer ref list(*)
               integer list_len, label_len, start_pos
```

DFANlastref/dalref

uint16 DFANlastref()

Purpose Returns the reference number of the annotation last written or read.

Return value Returns the reference number if successful and FAIL (or -1) otherwise.

FORTRAN integer function dalref()

DFANputdesc/dapdesc

int DFANputdesc(char *filename, uint16 tag, uint16 ref, char *description, int32 desc_len)

filename IN: Name of the file

tag IN: Tag of the data object to be assigned the description

ref IN: Reference number the data object to be assigned the description

description IN: Sequence of ASCII characters (may include NULL or '\0')

desc_len IN: Length of the description

Purpose Writes a description for the data object with the given tag and reference

number.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description The parameter description can contain any sequence of ASCII characters; it

does not have to be a string. If **DFANputdesc** is called more than once for the same tag/reference number pair, only the last description is stored in the file.

FORTRAN integer function dapdesc(filename, tag, ref, description,

desc_len)

character*(*) filename, description

integer tag, ref, desc_len

DFANputlabel/daplab

intn DFANputlabel(char *filename, uint16 tag, uint16 ref, char *label)

filename IN: Name of the file

tag IN: Tag of the data object to be assigned the label

ref IN: Reference number the data object to be assigned the label

label IN: Null-terminated label string

Purpose Assigns a label to the data object with the given tag/reference number pair.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

FORTRAN integer function daplab(filename, tag, ref, label)

character*(*) filename, label

integer tag, ref

DFSDadddata/dsadata

intn DFSDadddata(char *filename, intn rank, int32 dimsizes[], VOIDP data)

filename IN: Name of the HDF file

rank IN: Number of dimensions in the data array to be written

dimsizes IN: Array containing the size of each dimension

data IN: Array containing the data to be stored

Purpose Appends a scientific dataset in its entirety to an existing HDF file if the file

exists. If not, a new file is created.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description In addition to appending a multidimensional array of data to an HDF file,

DFSDadddata automatically stores any information pertinent to the dataset. It will not overwrite existing data in the file. The array data can be of any valid type. However, if no data type has been set by **DFSDsetNT**, it is assumed that

the data is of type float32.

Calling **DFSDadddata** will write the scientific dataset and all associated information. That is, when **DFSDadddata** is called, any information set by a

DFSDset* call is written to the file, along with the data array itself.

FORTRAN integer function dsadata(filename, rank, dimsizes, data)

character*(*) filename

integer rank

integer dimsizes(*), data(*)

DFSDclear/dsclear

intn DFSDclear()

Purpose Clears all values set by DFSDset* routines.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description After a call to **DFSDclear**, values set by any **DFSDset*** call will not be written

unless they have been set again.

FORTRAN integer function dsclear()

DFSDendslab/dseslab

intn DFSDendslab()

Purpose Terminates a sequence of slab calls started by DFSDstartslab by closing the

file.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

FORTRAN integer function dseslab()

DFSDendslice/dseslc

intn DFSDendslice()

Purpose Terminates the write operation after storing a slice of data in a scientific

dataset.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description DFSDendslice must be called after all the slices are written. It checks to ensure

that the entire dataset has been written, and if it has not, returns an error code. **DFSDendslice** is obsolete in favor of **DFSDendslab**. **DFSDendslab** is the recommended function call to use when terminating hyperslab (previously known as data slices) operations. HDF will continue to support **DFSDendslice** only to maintain backward compatibility with earlier versions of the library.

FORTRAN integer function dseslc()

DFSDgetcal/dsgcal

int32 DFSDgetcal(float64 *cal, float64 *cal_err, float64 *offset, float64 *offset_err, int32 *data_type)

OUT: Calibration factor cal cal_err OUT: Calibration error offset OUT: Uncalibrated offset offset_err OUT: Uncalibrated offset error data_type OUT: Data type of uncalibrated data

Retrieves the calibration record, if there is one, attached to a scientific dataset. **Purpose**

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description A calibration record contains four 64-bit floating point values followed by a

32-bit integer.

The relationship between a value iy stored in a dataset and the actual value y is defined as:

y = cal * (iy - offset)

The variable offset err contains a potential error of *offset*, and *cal_err* contains a potential error of cal. Currently the calibration record is provided for information only. The SD interface performs no operations on the data based on the calibration tag.

As an example, suppose the values in the calibrated dataset iy[] are the following integers:

 $iy[6] = \{2, 4, 5, 11, 26, 81\}$

By defining cal = 0.50 and offset = -200.0 and applying the calibration formula, the calibrated dataset iy[] returns to its original form as a floating point array:

 $y[6] = \{1001.0, 1002.0, 1002.5, 1005.5, 1013.0, 1040.5\}$

FORTRAN integer function dsgcal(cal, cal err, offset, offset err, data_type)

real cal, cal_err, offset, offset_err

integer data_type

DFSDgetdata/dsgdata

intn DFSDgetdata(char *filename, intn rank, int32 dimsizes[], VOIDP data)

filename IN: Name of the file

rank IN: Number of dimensions

dimsizes IN: Dimensions of the data buffer

data OUT: Buffer for the data

Purpose Reads the next dataset in the file.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description If the values of *rank* or *dimsizes* aren't known, **DFSDgetdims** must be called

to retrieve them and then use them to determine the buffer space needed for the array data. If the data type of the data in a scientific dataset isn't know, **DFSDgetNT** must be called to retrieve it. Subsequent calls to **DFSDgetdata** (or to **DFSDgetdims** and **DFSDgetdata**) will sequentially read scientific datasets from the file. For example, if **DFSDgetdata** is called three times in succession, the third call reads data from the third scientific dataset in the file.

If **DFSDgetdims** or **DFSDgetdata** is called and there are no more scientific datasets left in the file, an error code is returned and nothing is read.

DFSDrestart can be used to override this convention.

FORTRAN integer function dsgdata(filename, rank, dimsizes, data)

character*(*) filename

integer rank

integer dimsizes(*), data(*)

DFSDgetdatalen/dsgdaln

intn DFSDgetdatalen(intn *label_len, intn *unit_len, intn *format_len, intn *coords_len)

 label_len
 OUT:
 Maximum length of the label string

 unit_len
 OUT:
 Maximum length of the unit string

format_len OUT: Maximum length of the format string

coords_len OUT: Maximum length of the coordinate system string

Purpose Retrieves the lengths of the label, unit, format, and coordinate system strings.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description The space allocated for the label, unit, format, and coordinate system strings

must be at least one byte larger than the actual length of the string to account

for the null termination.

 $\begin{tabular}{ll} FORTRAN & integer function $dsgdaln(label_len, unit_len, format_len, $coords_len) \end{tabular}$

integer label_len, unit_len, format_len, coords_len

DFSDgetdatastrs/dsgdast

intn DFSDgetdatastrs(char *label, char *unit, char *format, char *coordsys)

label OUT: Label describing the data

unit OUT: Unit to be used with the data

format OUT: Format to be used in displaying data

coordsys OUT: Coordinate system

Purpose Retrieves information about the label, unit, and format attribute strings

associated with the data.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description The parameter *coordsys* gives the coordinate system that is to be used for

interpreting the dimension information.

FORTRAN integer function dsgdast(label, unit, format, coordsys)

character*(*) label, unit, format, coordsys

DFSDgetdimlen/dsgdiln

intn DFSDgetdimlen (intn dim, intn *label_len, intn *unit_len, intn *format_len)

dim IN: Dimension the label, unit, and format refer to

label_lenOUT:Length of the labelunit_lenOUT:Length of the unitformat_lenOUT:Length of the format

Purpose Retrieves the length of the label, unit, and format attribute strings associated

with the specified dimension.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description The space allocated to hold the label, unit, and format strings must be at least

one byte larger than the actual length of the string, to account for the null

termination.

FORTRAN integer function dsgdiln(dim, label_len, unit_len, format_len)

integer dim, label_len, unit_len, format_len

DFSDgetdims/dsgdims

intn DFSDgetdims(char *filename, intn *rank, int32 dimsizes[], intn maxrank)

filename IN: Name of the HDF file

rank OUT: Number of dimensions

dimsizes OUT: Buffer for the returned dimensions

maxrank IN: Size of the storage buffer dimsizes

Purpose Retrieves the number of dimensions (rank) of the dataset and the sizes of the

dimensions (dimsizes) for the next scientific dataset in the file.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description The *maxrank* parameter tells **DFSDgetdims** the size of the array that is

allocated for storing the *dimsizes* array. The value of *rank* must not exceed the

value of maxrank.

The allocation of a buffer for the scientific dataset data should correspond to the values retrieved by **DFSDgetdims**. The first value in the array *dimsizes* should equal the first dimension of the array that is allocated to hold the dataset; the second value in *dimsizes* should equal the second dimension of the

dataset, and so forth.

FORTRAN integer function dsgdims(filename, rank, dimsizes, maxrank)

character*(*) filename
integer rank, maxrank

integer dimsizes(*)

DFSDgetdimscale/dsgdisc

intn DFSDgetdimscale(intn dim, int32 size, VOIDP scale)

dim IN: Dimension this scale corresponds to

size IN: Size of the scale buffer

scale OUT: Array of values defining reference points along a specified

dimension

Purpose Gets the scale corresponding to the specified dimension.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description The DFSD interface requires the dimension scales to be of the same data type

as the corresponding data. To store dimension scales of a different data type

than the corresponding data, use the multifile SD interface.

FORTRAN integer function dsgdisc(dim, size, scale)

integer dim, size
integer scale(*)

DFSDgetdimstrs/dsgdist

intn DFSDgetdimstrs(intn dim, char *label, char *unit, char *format)

dim IN: Dimension this label, unit and format refer to

label OUT: Label that describes this dimension

unit OUT: Unit to be used with this dimension

format OUT: Format to be used in displaying scale for this dimension

Purpose Retrieves the label, unit, and format attribute strings corresponding to the

specified dimension.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description The space allocated for the label, unit, and format string must be at least one

byte larger than the length of the string to accommodate the null termination. If the length is unknown when the program is written, declare the array size as 1+maxlen label, maxlen unit, or maxlen format after they are set by

DFSDsetlengths. The maximum default string length is 255.

FORTRAN integer function dsgdist(dim, label, unit, format)

integer dim

character*(*) label, unit, format

DFSDgetfillvalue/dsgfill

intn DFSDgetfillvalue(VOIDP fill_value)

fill_value OUT: Fill value

Purpose Retrieves the fill value of a DFSD scientific dataset.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description The fill value is set by **DFSDsetfillvalue** and returned in the variable

fill_value. Note that **DFSDgetfillvalue** does not take a file name as an argument. As a result, a DFSD call to initialize the file information structures is required before calling **DFSDgetfillvalue**. One such call is **DFSDgetdims**.

FORTRAN integer function dsgfill(fill_value)

character*(*) fill_value

DFSDgetNT/dsgnt

intn DFSDgetNT(int32 *data_type)

data_type OUT: Data type of data in the scientific dataset

Purpose Retrieves the data type of the next dataset to be read.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description Note that **DFSDgetNT** does not take a file name as an argument. As a result, a

DFSD call to initialize the file information structures is required before calling

DFSDgetNT. One such call is **DFSDgetdims**.

Valid values for *data_type* are of the general form DFNT_. The following are valid symbolic names and their data types:

32-bit float	DFNT_FLOAT32	5
64-bit float	DFNT_FLOAT64	6
8-bit signed int	DFNT_INT8	20
8-bit unsigned int	DFNT_UINT8	21
16-bit signed int	DFNT_INT16	22
16-bit unsigned int	DFNT_UINT16	23
32-bit signed int	DFNT_INT32	24
32-bit unsigned int	DFNT_UINT32	25
8-bit character	DFNT_CHAR8	4

FORTRAN integer function dsgnt(num_type)

integer num_type

DFSDgetrange/dsgrang

intn DFSDgetrange(VOIDP max, VOIDP min)

max OUT: Maximum value stored with the scientific dataset

min OUT: Maximum value stored with the scientific dataset

Purpose Retrieves the maximum and minimum values stored with the scientific dataset.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description The *max* and *min* values are set via a call to **DFSDsetrange**. They are not

automatically stored when a dataset is written to a file. The data type of these values is the data type of the dataset array. One implication of this is that in the C version of **DFSDgetrange** the arguments are pointers, rather than simple variables, whereas in the FORTRAN-77 version they are simple variables of

the same type as the data array.

Neither **DFSDgetrange** nor **DFSDgetdata** compare the *max* and *min* values stored with the dataset to the actual values in the dataset; they merely retrieve the data. As a result, the maximum and minimum values may not always reflect the actual maximum and minimum values in the dataset. In some cases the *max* and *min* values may actually lie outside the range of values in the

dataset.

FORTRAN integer function dsgrang(max, min)

character*(*) max, min

DFSDgetslice/dsgslc

intn DFSDgetslice(char *filename, int32 winst[], int32 windims[], VOIDP data, int32 dims[])

filename IN: Name of HDF file

winst IN: Array containing the coordinates for the start of the slice

windim IN: Array containing the dimensions of the slice

data OUT: Array for returning slice

dims OUT: Dimensions of array data

Purpose Reads part of a scientific dataset from a file.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description

DFSDgetslice accesses the dataset last accessed by **DFSDgetdims**. If **DFSDgetdims** has not been called for the named file, **DFSDgetslice** gets a slice from the next dataset in the file. Array *winst* specifies the coordinates of the start of the slice. Array *windims* gives the size of the slice. The number of elements in *winst* and *windims* must be equal to the rank of the dataset. For example, if the file contains a three-dimensional dataset, *winst* may contain the values {2, 4, 3}, while windims contains the values {3, 1, 4} and the dims should be at least {3, 1, 4}, the same size as the slice. This will extract a 3 x 4, two-dimensional slice, containing the elements between (2, 4, 3) and (4, 4, 6) from the original dataset.

The *data* array is the array into which the slice is read. It must be at least as big as the desired slice. The *dims* array is the array containing the actual dimensions of the array *data*. The user assigns values to *dims* before calling **DFSDgetslice**.

All parameters assume FORTRAN-77-style one-based arrays.

DFSDgetslice is obsolete in favor of **DFSDreadslab**. **DFSDreadslab** is the recommended function call to use when reading hyperslabs (previously known as data slices). HDF will continue to support **DFSDgetslice** only to maintain backward compatibility with HDF applications built on earlier versions of the library.

FORTRAN

```
integer function dsgslc(filename, winst, windims, data, dims)
```

```
character*(*) filename, data
```

integer winst(*), windims(*), dims(*)

DFSDlastref/dslref

intn DFSDlastref()

Purpose Retrieves the most recent reference number used in writing or reading a

scientific dataset.

Return value Returns the reference number for the last accessed scientific dataset if

successful and FAIL (or -1) otherwise.

Description DFSDlastref returns the value of the last reference number of a scientific

dataset read from or written to the file.

FORTRAN integer function dslref()

DFSDndatasets/dsnum

intn DFSDndatasets(char *filename)

filename IN: Name of the HDF file

Purpose Returns the number of scientific datasets in the file.

Return value Returns the number of datasets if successful and FAIL (or -1) otherwise.

Description In HDF version 3.3, **DFSDndatasets** replaced **DFSDnumber**. In order to

maintain backward compatibility with existing HDF applications, HDF will continue to support **DFSDnumber**. However, it is recommended that all new

applications use **DFSDndatasets** instead of **DFSDnumber**.

FORTRAN integer function dsnum(filename)

character*(*) filename

DFSDpre32sdg/dsp32sd

intn DFSDpre32sdg(char *filename, uint16 ref, intn *ispre32)

filename IN: The name of the HDF file containing the scientific dataset

ref IN: Reference number of SDG

ispre32 OUT: Pointer to results of the pre-HDF version 3.2 inquiry

Purpose Tests if the scientific dataset with the specified reference number was created

by an HDF library earlier than version 3.2.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description If the scientific dataset was created with a version of HDF prior to version 3.2,

ispre32 will be set to 1, otherwise it will be set to 0. Based on this information, programmers can decide whether or not to transpose the corresponding array.

FORTRAN integer function dsp32sd(filename, ref, ispre32)

character*(*) filename

integer ref, ispre32

DFSDputdata/dspdata

intn DFSDputdata(char *filename, intn rank, int32 dimsizes[], VOIDP data)

filename IN: Name of the HDF file

rank IN: Number of dimensions of data array to be stored

dimsizes IN: Buffer for the dimension sizes

data IN: Buffer for the data to be stored

Purpose Writes a scientific data and related information to an HDF file.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description DFSDputdata will write data to an existing file by destroying the contents of

the original file. Use it with caution. If a new filename is used, DFSDputdata

functions exactly like DFSDadddata.

FORTRAN integer function dspdata(filename, rank, dimsizes, data)

character*(*) filename

<valid numeric data type> data

integer rank

integer dimsizes(*)

DFSDputslice/dspslc

intn DFSDputslice(int32 windims[], VOIDP source, int32 dims[])

windims IN: Window dimensions specifying the size of the slice to be written

source IN: Buffer for the slice

dims IN: Dimensions of the source array

Purpose Writes part of a scientific dataset to a file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description DFSDputslice read a subset of an array in memory and stores it as part of the scientific dataset array last specified by **DFSDsetdims**. Slices must be stored

contiguously.

Array windims ("window dimensions") specifies the size of the slice to be written. The windims array must contain as many elements as there are dimensions in the entire scientific dataset array. The source argument is an array in memory containing the slice and dims is an array containing the dimensions of the array source.

Notice that *windims* and *dims* need not be the same. The *windims* argument could refer to a sub-array of *source*, in which case only a portion of *source* is written to the scientific data array.

All parameters assume FORTRAN-77-style one-based arrays.

DFSDputslice is obsolete in favor of **DFSDwriteslab**. **DFSDwriteslab** is the recommended function call to use when writing hyperslabs (previously known as data slices). HDF will continue to support **DFSDputslice** only to maintain backward compatibility with earlier versions of the library.

DFSDreadref/dsrref

intn DFSDreadref(char *filename, uint16 ref)

filename IN: Name of the HDF file

ref IN: Reference number for next **DFSDgetdata** call

Purpose Specifies the reference number for the dataset to be read during the next read

operation.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description This routine is commonly used in conjunction with **DFANgetlablist**, which

returns a list of labels for a given tag together with their reference numbers. It

provides a sort of random access to scientific datasets.

There is no guarantee that reference numbers appear in sequence in an HDF

file, so it is not generally safe to assume that a reference number is an index

number of a scientific dataset.

FORTRAN integer function dsrref(filename, ref)

character*(*) filename

integer ref

DFSDreadslab/dsrslab

intn DFSDreadslab(char *filename, int32 start[], int32 slab_size[], int32 stride[], VOIDP buffer, int32 buffer_size[])

filename IN: Name of the HDF file

start IN: Buffer of size rank containing the coordinates for the start of the slab

slab_size IN: Buffer of size rank containing the size of each dimension in the slab

stride IN: Subsampling (not yet implemented)

buffer OUT: \Buffer for the returned slab

buffer_size OUT: Dimensions of the buffer parameter

Purpose Reads a slab of data from any scientific dataset.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description

DFSDreadslab will access to the scientific dataset following the current one if **DFSDgetdims** or **DFSDgetdata** are not called earlier. The *start* array indices are one-based. The rank of *start* must be the same as the number of dimensions of the specified variable. The elements of *slab_size* must be no larger than the dimensions of the scientific dataset in order. The stride feature is not currently implemented. For now just pass the *start* array as the argument for *stride* where it will be ignored.

To extract a slab of lower dimension than that of the dataset, enter 1 in the $slab_size$ array for each omitted dimension. For example, to extract a two-dimensional slab from a three-dimensional dataset, specify the beginning coordinates in three dimensions and enter a 1 for the missing dimension in the $slab_size$ array. More specifically, to extract a 3×4 slab containing the elements (6, 7, 8) through (8, 7, 11) specify the beginning coordinates as {6, 7, 8} and the slab size as {3, 1, 4}.

FORTRAN

```
character*(*) filename, buffer
integer start(*), slab_size(*),
integer stride(*), buffer_size(*)
```

DFSDrestart/dsfirst

intn DFSDrestart()

Purpose Causes the next read command to be read from the first scientific dataset in the

file, rather than the scientific dataset following the one that was most recently

read.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

FORTRAN integer function dsfirst()

DFSDsetcal/dsscal

intn DFSDsetcal(float64 cal, float64 cal_err, float64 offset, float64 offset_err, int32 data_type)

cal IN: Calibration factor

cal_err IN: Calibration error

offset IN: Uncalibrated offset

offset_err IN: Uncalibrated offset error

data_type IN: Data type of uncalibrated data

Purpose Sets the calibration information associated with data

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description

This routine sets the calibration record associated with a dataset. A calibration record contains four 64-bit floating point values followed by a 32-bit integer, to be interpreted as follows:

cal calibration factor
cal_err calibration error
offset uncalibrated offset
offset_err uncalibrated offset error
data_type data type of uncalibrated data

The relationship between a value iy stored in a dataset and the actual value y is defined as:

```
y = cal * (iy - offset)
```

The variable offset_err contains a potential error of offset, and cal_err contains a potential error of cal. Currently the calibration record is provided for information only. The SD interface performs no operations on the data based on the calibration tag.

DFSDsetcal works like other **DFSDset*** routines, with one exception: the calibration information is automatically cleared after a call to **DFSDputdata** or **DFSDadddata**. Hence, **DFSDsetcal** must be called again for each dataset that is to be written.

As an example, suppose the values in a dataset y[] are as follows:

```
y[6] = \{1001.0, 1002.0, 1002.5, 1005.5, 1013.0, 1040.5\}
```

By defining cal = 0.50 and offset = -200.0 and applying the calibration formula, the calibrated dataset iy[] becomes as follows:

```
iy[6]={2, 4, 5, 11, 26, 81}
```

The array iy [] can then be stored as integers.

FORTRAN

integer function dsscal(cal, cal_err, offset, offset_err, data_type)

real*8 cal, cal_err, offset, offset_err

integer data_type

DFSDsetdatastrs/dssdast

intn DFSDsetdatastrs(char *label, char *unit, char *format, char *coordsys)

label IN: Label describing the data

unit IN: Unit to be used with the data

format IN: Format to be used in displaying the data

coordsys IN: Coordinate system of the data

Purpose Sets the label, unit, format, and coordinate system for the next dataset written

to file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

FORTRAN integer function dssdast(label, unit, format, coordsys)

character*(*) label, unit, format, coordsys

DFSDsetdims/dssdims

intn DFSDsetdims (intn rank, int32 dimsizes[])

rank IN: Number of dimensions

dimsizes IN: Dimensions of the scientific dataset

Purpose Sets the rank and dimension sizes for all subsequent scientific datasets written

to the file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description This routine must be called before calling either **DFSDsetdimstrs** or

DFSDsetdimscale. **DFSDsetdims** need not be called if other set routines are

not called and the correct dimensions are supplied in **DFSDputdata** or **DFSDpddd**

DFSDadddata.

If the rank or dimension sizes change, all previous set calls are cleared, except

for the data type, which is set by calling **DFSDsetNT**.

FORTRAN integer function dssdims(rank, dimsizes)

integer rank

integer dimsizes(*)

DFSDsetdimscale/dssdisc

intn DFSDsetdimscale (intn dim, int32 dimsize, VOIDP scale)

dim IN: Dimension this scale corresponds to

dimsize IN: Size of the scale buffer

scale IN: Buffer for the scale values

Purpose Defines the scale for a dimension.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description A scale is a one-dimensional array whose values describe reference points

along one dimension of the dataset. For example, a two-dimensional dataset representing points on a map could have two scales, one representing points of

latitude, and the other points of longitude.

FORTRAN integer function dssdisc (dim, dimsize, scale)

integer dim

integer dimsize(*), scale(*)

DFSDsetdimstrs/dssdist

intn DFSDsetdimstrs(intn dim, char *label, char *unit, char *format)

dim IN: Dimension this label, unit and format refer to

label IN: Label that describes this dimension

unit IN: Unit to be used with this dimension

format IN: Format to be used to display scale

Purpose Sets the label, unit, and format strings corresponding to the specified

dimension.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description In both FORTRAN-77 and C programs, dim = 1 for the first dimension, and

dim = 2 for the second dimension. If the user is not interested in one or more strings, empty strings can be used as parameters for the **DFSDsetdimstrs** call. For example, **DFSDsetdimstrs**(1, "vertical", "", "") will set the label for the first dimension to "vertical" and set the unit and format to empty strings.

FORTRAN integer function dssdist(dim, label, unit, format)

integer dim

character*(*) label, unit, format

DFSDsetfillvalue/dssfill

intn DFSDsetfillvalue(VOIDP fill_value)

fill_value IN: Fill value

Purpose Set the value used to fill in any unwritten location in a scientific dataset.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description It is assumed that the fill value has the same data type as the dataset. Once the

fill value is set for a particular SDS, it cannot be changed.

If **DFSDsetfillvalue** is called before the first call to **DFSDstartslab**, **DFSDstartslab** will set the fill value tag attribute to the value specified in the **DFSDsetfillvalue** call, but will not actually write out the fill value when **DFSDwriteslab** is called. However, if **DFSDsetfillvalue** is called after the first call the **DFSDstartslab**, the fill value tag attribute will be set by **DFSDsetfillvalue** and the fill value will be written to the slab during the

DFSDwriteslab call.

FORTRAN integer function dssfill(fill_value)

character*(*) fill_value

DFSDsetlengths/dsslens

intn DFSDsetlengths(intn label_len, intn unit_len, intn format_len, intn coords_len)

label_len IN: Maximum length of label strings

unit_len IN: Maximum length of unit strings

format_len IN: Maximum length of format strings

coords_len IN: Maximum length of coordinate system strings

Purpose Sets the maximum lengths for the strings that will hold labels, units, formats,

and the name of the coordinate system.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description The lengths set by this routine are used by the routines **DFSDgetdimstrs** and

DFSDgetdatastrs to determine the maximum lengths of strings that they get

from the file.

Normally, DFSDsetlengths is not needed. If it is not called, default maximum

lengths of 255 are used for all strings.

FORTRAN integer function dsslens(label_len, unit_len, format_len,

coords_len)

integer label len, unit len, format len, coords len

DFSDsetNT/dssnt

intn DFSDsetNT(int32 data_type)

data_type IN: Data type

Purpose Sets the data type of the data to be written in the next write operation.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description DFSDsetNT must be called if a data type other than float32 is to be stored. **DFSDsetNT** and **DFSDsetdims** can be called in any order, but they should be

called before any other **DFSDset*** functions and before **DFSDputdata** or

DFSDadddata.

The following symbolic names can be used as the value of *data_type*:

32-bit float	DFNT_FLOAT32	5
64-bit float	DFNT_FLOAT64	6
8-bit signed int	DFNT_INT8	20
8-bit unsigned int	DFNT_UINT8	21
16-bit signed int	DFNT_INT16	22
16-bit unsigned int	DFNT_UINT16	23
32-bit signed int	DFNT_INT32	24
32-bit unsigned int	DFNT_UINT32	25
8-bit character	DFNT_CHAR8	4

FORTRAN integer function dssnt(num_type)

integer num_type

DFSDsetrange/dssrang

intn DFSDsetrange(VOIDP max, VOIDP min)

max IN: Highest value in the range

min IN: Lowest value in the range

Purpose Stores the specified maximum and minimum data values.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description It is assumed that the data type of *max* and *min* is the same as the type of the

data. One implication of this is that in the C version of **DFSDsetrange** the arguments are pointers, rather than simple variables, whereas in the

FORTRAN-77 version they are simple variables of the same type as the data

array.

This routine does not compute the maximum and minimum values; it merely stores the values it is given. As a result, the maximum and minimum values may not always reflect the actual maximum and minimum values in the data

array.

When the maximum and minimum values are written to a file, the HDF element that holds these values is cleared, because it is assumed that subsequent datasets will have different values for max and min.

FORTRAN integer function dssrang(max, min)

character*(*) max, min

DFSDstartslab/dssslab

intn DFSDstartslab(char *filename)

IN: Name of the HDF file filename

Purpose Prepares the DFSD interface to write a slab of data to a scientific dataset.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description

DFSDsetdims must be called before calling **DFSDstartslab**. No call which involves a file open may be made after a **DFSDstartslab** call until **DFSDendslab** is called. This routine will write out the fill values if

DFSDsetfillvalue is called before this routine.

FORTRAN integer function dssslab(filename)

character*(*) filename

2-331 **December 30, 2003**

DFSDstartslice/dssslc

intn DFSDstartslice(char *filename)

filename IN: Name of the HDF file

Purpose Prepares the interface to write a data slice to the specified file.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description Before calling **DFSDstartslice**, **DFSDsetdims** must be called to specify the

dimensions of the dataset to be written to the file. **DFSDstartslice** always

appends a new dataset to an existing file.

Also, **DFSDstartslice** must be called before **DFSDputslice** or **DFSDendslice**.

DFSDstartslab is the recommended function call to use when beginning hyperslab operations. HDF

will continue to support DFSDstartslice only to maintain backward

compatibility earlier versions of the library.

FORTRAN integer function dssslc(filename)

character*(*) filename

DFSDwriteref/dswref

intn DFSDwriteref(char *filename, uint16 ref)

filename IN: Name of the HDF file

ref IN: Reference number for next add or put operation

Purpose Specifies the reference number, *ref*, of the dataset to be overwritten next by

DFSDputdata or DFSDadddata.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description DFSDwriteref verifies the refence number's existence before returning. If a

non-existent reference number is specified, an error code will be returned.

As this routine alters data in a destructive manner, **DFSDwriteref** should be

used with caution.

FORTRAN integer function dswref(filename, ref)

character*(*) filename

integer ref

DFSDwriteslab/dswslab

intn DFSDwriteslab(int32 start[], int32 stride[], int32 count[], VOIDP data)

start IN: Array containing the starting coordinates of the slab

stride IN: Array containing the dimensions for subsampling

count IN: Array containing the size of the slab

data IN: Array to hold the floating point data to be written

Purpose Writes a slab of data to a scientific dataset.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

Description The *start* indices are relative to 1. The rank of *start* must be the same as the

number of dimensions of the specified variable. The elements of *start* must be no larger than the scientific dataset's dimensions in order. The stride feature is not currently implemented. For now just pass the *start* array as the argument

for the *stride* parameter, where it will be ignored.

The rank of *count* must be the same as the number of dimensions of the specified variable. The elements of *count* must be no larger than the scientific dataset's dimensions in order. The order in which the data will be written into the specified hyperslab is with the last dimension varying fastest. The data should be of the appropriate type for the dataset. Note that neither the compiler

nor HDF software can detect if the wrong type of data is used.

FORTRAN integer function dswslab(start, stride, count, data)

integer start(*), stride(*), count(*)

character*(*) data

HDF Reference Manual Happendable

Happendable

intn Happendable(int32 *h_id*)

 h_{id} IN: Access identifier returned by **Hstartwrite**

Purpose Specifies that the specified element can be appended to

Return value Returns Succeed (or 0) if data element can be appended and FAIL (or -1)

otherwise.

Description If a data element is at the end of a file **Happendable** allows **Hwrite** to append

data to it, converting it to linked-block element only when necessary.

Hcache

intn Hcache(int32 file_id, intn cache_switch)

file_id IN: File identifier returned by **Hopen**

cache_switch IN: Flag to enable or disable caching

Purpose Enables low-level caching for the specified file.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description If *file_id* is set to CACHE_ALL_FILES, then the value of *cache_switch* is used to

modify the default file cache setting.

Valid values for cache_switch are: TRUE (or 1) to enable caching and FALSE (or

0) to disable caching.

HDF Reference Manual Hdeldd

Hdeldd

intn Hdeldd(int32 file_id, uint16 tag, uint16 ref)

file_id IN: File identifier returned by **Hopen**

tag IN: Tag of data descriptor to be deleted

ref IN: Reference number of data descriptor to be deleted

Purpose Deletes a tag and reference number from the data descriptor list.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description Once the data descriptor is removed, the data in the data object becomes inaccessible and is marked as such. To remove inaccessible data from an HDF

file, use the utility hdfpack.

Hdeldd only deletes the specified tag and reference number from the data descriptor list. Data objects containing the deleted tag and reference number are not automatically updated. For example, if the tag and reference number deleted from the descriptor list referenced an object in a vgroup, the tag and reference number will still exist in the vgroup even though the data is inaccessible.

Hendaccess

intn Hendaccess(int32 *h_id*)

h_id IN: Access identifier returned by **Hstartread**, **Hstartwrite**, or

Hnextread

Purpose Terminates access to a data object by disposing of the access identifier.

Return value Returns SUCCEED (or 0) if successful and FAIL (or -1) otherwise.

DescriptionThe number of active access identifiers is limited to MAX_Acc as defined in the hlimits.h header file. Because of this restriction, it is very important to call **Hendaccess** immediately following the last operation on a data element.

When developing new interfaces, a common mistake is to omit calling **Hendaccess** for all of the elements accessed. When this happens, **Helose** will return FAIL, and a dump of the error stack will report the number of active access identifiers. Refer to the Reference Manual page on **HEprint**.

This is a difficult problem to debug because the low levels of the HDF library cannot determine who and where an access identifier was originated. As a result, there is no automated method of determining which access identifiers have yet to be released.

HDF Reference Manual Hendbitaccess

Hendbitaccess

intn Hendbitaccess(int32 *h_id*, intn *flushbit*)

h_id IN: Identifier of the bit-access element to be disposed of

flushbit IN: Specifies how the leftover bits are to be flushed

Purpose Disposes of the specified bit-access file element.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description If called after a bit-write operation, **Hendbitaccess** flushes all buffered bits to

the dataset, then calls Hendaccess.

"Leftover bits" are bits that have been buffered, but are fewer than the number

of bits defined by BITNUM, which is usually set to 8.

Valid codes for flushbit are: 0 for flush with zeros, 1 for flush with ones and -1

for dispose of leftover bits

Hexist

intn Hexist(int32 h_id, uint16 search_tag, uint16 search_ref)

h_id IN: Access identifier returned by **Hstartread**, **Hstartwrite**, or

Hnextread

search_tag IN: Tag of the object to be searched for

search_ref IN: Reference number of the object to be searched for

Purpose Locates an object in an HDF file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description Simple interface to **Hfind** that determines if a given tag/reference number pair

exists in a file. Wildcards apply.

Hfind performs all validity checking; this is just a very simple wrapper around

it.

HDF Reference Manual Hfidinquire

Hfidinquire

intn Hfidinquire(int32 file_id, char *filename, intn *access, intn *attach)

file_id IN: File identifier returned by **Hopen**

filename OUT: Complete path and filename for the file

access OUT: Access mode file is opened with

attach OUT: Number of access identifiers attached to the file

Purpose Returns file information through a reference of its file identifier.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description Gets the complete path name, access mode, and number of access identifiers

associated with a file. The *filename* parameter is a pointer to a character pointer which will be modified when the function returns. Upon completion, *filename* is set to point to the file name in internal storage. All output parameters must

be non-null pointers.

Hfind

intn Hfind(int32 file_id, uint16 search_tag, uint16 search_ref, uint16 *find_tag, uint16 *find_ref, int32 *find_offset, int32 *find_length, intn direction)

file_id	IN:	File identifier returned by Hopen
search_tag	IN:	The tag to search for or DFTAG_WILDCARD
search_ref	IN:	Reference number to search for or DFREF_WILDCARD
find_tag	IN/OUT:	If $(*find_tag == 0)$ and $(*find_ref == 0)$ then start the search from either the beginning or the end of the file. If the object is found, the tags of the object will be returned here.
find_ref	IN/OUT:	If $(*find_tag == 0)$ and $(*find_ref == 0)$ then start the search from either the beginning or the end of the file. If the object is found, the reference numbers of the object will be returned here.
find_offset	OUT:	Offset of the data element found
find_length	OUT:	Length of the data element found
direction	IN:	Direction to search in DF_FORWARD searches forward from the current location, and DF_BACKWARD searches backward from the current location

Purpose Locates the next object to be searched for in an HDF file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description Hfind searches for the next data element that matches the specified tag and reference number. Wildcards apply. If *direction* is DF_FORWARD, searching is forward from the current position in the file, otherwise DF_BACKWARD specifies backward searches from the current position in the file.

If *find_tag* and *find_ref* are both set to 0, this indicates the beginning of a search, and the search will start from the beginning of the file if the direction is DF_FORWARD and from the end of the file if the direction is DF_BACKWARD.

HDF Reference Manual Hgetbit

Hgetbit

intn Hgetbit(int32 *h_id*)

h_id IN: Bit-access element identifier

Purpose Reads one bit from the specified bit-access element.

Return value Returns the bit read (or 0 or 1) if successful and FAIL (or -1) otherwise.

Description This function is a wrapper for **Hbitread**.

Hgetelement

int32 Hgetelement(int32 file_id, uint16 tag, uint16 ref, uint8 *data)

file_id IN: File identifier returned by **Hopen**

tag IN: Tag of the data element to be read

ref IN: Reference number of the data element to be read

data OUT: Buffer the element will be read into

Purpose Reads the data element for the specified tag and reference number and writes it

to the data buffer.

Return value Returns the number of bytes read if successful and FAIL (or -1) otherwise.

Description It is assumed that the space allocated for the buffer is large enough to hold the

data.

HDF Reference Manual Hinquire

Hinquire

intn Hinquire(int32 h_id , int32 * $file_id$, uint16 *tag, uint16 *ref, int32 *length, int32 *offset, int32 *position, int16 *access, int16 *special)

h_id	IN:	Access identifier returned by Hstartread , Hstartwrite , or Hnextread
file_id	OUT:	File identifier returned by Hopen
tag	OUT:	Tag of the element pointed to
ref	OUT:	Reference number of the element pointed to
length	OUT:	Length of the element pointed to
offset	OUT:	Offset of the element in the file
position	OUT:	Current position within the data element
access	OUT:	The access type for this data element
special	OUT:	Special code
Purpose	Returns access information about a data element.	
Return value	Returns Succeed (or 0) if the access identifier points to a valid data element and FAIL (or -1) otherwise.	
Description	If h_id is a valid access identifier the access type (read or write) is set regardless of whether or not the return value is FAIL (or -1). If h_id is invalid,	

excess information, pass NULL for any unnecessary pointer.

the function returns FAIL (or -1) and the access type is set to zero. To avoid

Hlength

int32 Hlength(int32 file_id, uint16 tag, uint16 ref)

file_id IN: File identifier returned by **Hopen**

tag IN: Tag of the data element

ref IN: Reference number of the data element

Purpose Returns the length of a data object specified by the tag and reference number.

Return value Returns the length of data element if found and FAIL (or -1) otherwise.

Description Hlength calls Hstartread, HQuerylength, and Hendaccess to determine the

length of a data element. Hlength uses Hstartread to obtain an access

identifier for the specified data object.

Hlength will return the correct data length for linked-block elements, however it is important to remember that the data in linked-block elements is not stored

contiguously.

HDF Reference Manual Hnewref

Hnewref

uint16 Hnewref(int32 file_id)

file_id IN: File identifier returned by **Hopen**

Purpose Returns a reference number that can be used with any tag to produce a unique

tag /reference number pair.

Return value Returns the reference number if successful and 0 otherwise.

Description Successive calls to Hnewref will generate reference number values that

increase by one each time until the highest possible reference number has been returned. At this point, additional calls to **Hnewref** will return an increasing

sequence of unused reference number values starting from 1.

Hnextread

intn Hnextread(int32 *h_id*, uint16 *tag*, uint16 *ref*, int *origin*)

 h_{id} IN: Access identifier returned by **Hstartread** or previous **Hnextread**

tag IN: Tag to search for

ref IN: Reference number to search for

origin IN: Position to begin search: DF_START or DF_CURRENT

Purpose Searches for the next data descriptor that matches the specified tag and

reference number.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description Wildcards apply. If origin is DF_START, the search will start at the beginning of

the data descriptor list. If origin is DF_CURRENT, the search will begin at the current position. Searching backwards from the end of a data descriptor list is

not yet implemented.

If the search is successful, the access identifier reflects the new data element,

otherwise it is not modified.

Hnumber/hnumber

int32 Hnumber(int32 file_id, uint16 tag)

file_id IN: File identifier returned by **Hopen**

tag IN: Tag to be counted

Purpose Returns the number of instances of a tag in a file.

Return value Returns the number of instances of a tag in a file if successful, and FAIL (or -1)

otherwise.

Description Hnumber determines how many objects with the specified tag are in a file. To

determine the total number of objects in a file, set the tag argument to

DFTAG_WILDCARD. Note that a return value of zero is not a fail condition.

FORTRAN integer function hnumber(file_id, tag)

integer file_id, tag

Hoffset

int32 Hoffset(int32 file_id, uint16 tag, uint16 ref)

file_id IN: File identifier returned by **Hopen**

IN: Tag of the data element tag

ref IN: Reference number of the data element

Purpose Returns the offset of a data element in the file.

Return value Returns the offset of the data element if the data element exists and FAIL (or -

1) otherwise.

Description Hoffset calls Hstartread, HQueryoffset, and Hendaccess to determine the

length of a data element. Hoffset uses Hstartread to obtain an access

identifier for the specified data object.

Hoffset will return the correct offset for a linked-block element, however it is important to remember that the data in linked-block elements is not stored contiguously. The offset returned by Hoffset only reflects the position of the

first data block.

Hoffset should not be used to determine the offset of an external element. In

this case, Hoffset returns zero, an invalid offset for HDF files.

HDF Reference Manual Hputbit

Hputbit

intn Hputbit(int32 *h_id*, intn *bit*)

 h_i IN: Bit-access element identifier

bit IN: Bit to be written

Purpose Writes one bit to the specified bit-access element.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description This function is a wrapper for **Hbitwrite**.

Hputelement

int32 Hputelement(int32 file_id, uint16 tag, uint16 ref, uint8 *data, int32 length)

file_id IN: File identifier returned by **Hopen**

tag IN: Tag of the data element to add or replace

ref IN: Reference number of the data element to add or replace

data IN: Pointer to data buffer length IN: Length of data to write

Purpose Writes a data element or replaces an existing data element in a HDF file.

Return value Returns the number of bytes written if successful and FAIL (or -1) otherwise.

HDF Reference Manual Hread

Hread

int32 Hread(int32 *h_id*, int32 *length*, VOIDP *data*)

 h_{id} IN: Access identifier returned by **Hstartread**, **Hstartwrite**, or

Hnextread

length IN: Length of segment to be read

data OUT: Pointer to the data array to be read

Purpose Reads the next segment in a data element.

Return value Returns the length of segment actually read if successful and FAIL (or -1)

otherwise.

Description Hread begins reading at the current file position, reads the specified number of bytes, and increments the current file position by one. Calling **Hread** with the

length = 0 reads the entire data element. To reposition an access identifier

before writing data, use Hseek.

If *length* is longer than the data element, the read operation is terminated at the end of the data element, and the number of read bytes is returned. Although only one access identifier is allowed per data element, it is possible to interlace reads from multiple data elements in the same file. It is assumed that data is

large enough to hold the specified data length.

Hseek

intn Hseek(int32 *h_id*, int32 *offset*, intn *origin*)

 h_{id} IN: Access identifier returned by **Hstartread**, **Hstartwrite**, or

Hnextread

offset IN: Number of bytes to seek to from the origin

origin IN: Position of the offset origin

Purpose Sets the access pointer to an offset within a data element.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description Sets the seek position for the next **Hread** or **Hwrite** operation by moving an access identifier to the specified position in a data element. The *origin* and the

offset arguments determine the byte location for the access identifier. If origin is set to DF_START, the offset is added to the beginning of the data element. If origin is set to DF_CURRENT, the offset is added to the current position of the

access identifier.

Valid values for origin are: DF_START (the beginning of the file) or DF_CURRENT

(the current position in the file).

This routine fails if the access identifier if h_id is invalid or if the seek position

is outside the range of the data element.

HDF Reference Manual Hsetlength

Hsetlength

int32 Hsetlength(int32 file_id, int32 length)

file_id IN: File identifier returned by **Hopen**

length IN: Length of the new element

Purpose Specifies the length of a new HDF element.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description This function can only be used when called after **Hstartaccess** on a new data

element and before any data is written to that element.

Hshutdown

int32 Hshutdown()

Purpose Deallocates buffers previously allocated in other H routines.

Return value Returns Succeed (or 0) if successful and Fail (or -1) otherwise.

Description Should only be called by the function **HDFend**.

HDF Reference Manual Htagnewref

Htagnewref

int32 Htagnewref(int32 *file_id*, uint16 *tag*)

file_id IN: Access identifier returned by **Hstartread** or **Hnextread**

tag IN: Tag to be identified with the returned reference number

Purpose Returns a reference number that is unique for the specified file that will

correspond to the specified tag. Creates a new tag/reference number pair.

Return value Returns the reference number if successful and 0 otherwise.

Description Successive calls to **Hnewref** will generate a increasing sequence of reference

number values until the highest possible reference number value has been returned. It will then return unused reference number values starting from 1 in

increasing order.

Htrunc

int32 Htrunc(int32 *h_id*, int32 *trunc_len*)

 h_i IN: Access identifier returned by **Hstartread** or **Hnextread**

trunc_len IN: Length to truncate element

Purpose Truncates the data object specified by the h_id to the length $trunc_len$.

Return value Returns the length of a data element if found and FAIL (or -1) otherwise.

Description Htrunc does not handle special elements.

HDF Reference Manual Hwrite

Hwrite

int32 Hwrite(int32 *h_id*, int32 *length*, VOIDP *data*)

 h_{id} IN: Access identifier returned by **Hstartwrite**

len IN: Length of segment to be written

data IN: Pointer to the data to be written

Purpose Writes the next data segment to a specified data element.

Return value Returns the length of the segment actually written if successful and FAIL (or -

1) otherwise.

Description Hwrite begins writing at the current position of the access identifier, writes the specified number of bytes, then moves the access identifier to the position

immediately following the last accessed byte. Calling **Hwrite** with length = 0 results in an error condition. To reposition an access identifier before writing

data, use Hseek.

If the space allocated in the data element is smaller than the length of data, the data is truncated to the length of the data element. Although only one access identifier is allowed per data element, it is possible to interlace writes to more

than one data element in a file.

HDFclose/hdfclose

intn HDFclose(int32 file_id)

file_id IN: File identifier returned by **Hopen**

Purpose Closes the access path to the file.

Return value Returns Succeed (or 0) if successful and FAIL (or -1) otherwise.

Description The file identifier *file_id* is validated before the file is closed. If the identifier is

valid, the function closes the access path to the file.

If there are still access identifiers attached to the file, the error code DFE_OPENAID is returned and the file is not closed. This is a common occurrence when developing new interfaces. See **Hendaccess** for further

discussion of this problem.

FORTRAN integer function hdfclose(file_id)

integer file_id

HDFopen/hdfopen

int32 HDFopen(char *filename, intn access, int16 n_dds)

filename IN: Complete path and filename for the file to be opened

access IN: File access code

n_dds IN: Number of data descriptors in a block if a new file is to be created

Purpose Provides an access path to an HDF file by reading all the data descriptor blocks

into memory.

Return value Returns the file identifier if successful and FAIL (or -1) otherwise.

Description If given a new file name, **HDFopen** will create a new file using the specified access type and number of data descriptors. If given an existing file name,

HDFopen will open the file using the specified access type and ignore the

n_dds argument.

HDF provides several file access code definitions:

DFACC_READ - Open for read only. If file does not exist, an error condition

esults.

DFACC_CREATE - If file exists, delete it, then open a new file for read/write.

DFACC_WRITE - Open for read/write. If file does not exist, create it.

If a file is opened and an attempt is made to reopen the file using DFACC_CREATE, HDF will issue the error DFE_ALROPEN. If the file is opened with read only access and an attempt is made to reopen the file for write access using DFACC_RDWR, DFACC_WRITE, or DFACC_ALL, HDF will attempt to reopen the file with read and write permissions.

Upon successful exit, the named file is opened with the relevant permissions, the data descriptors are set up in memory, and the associated *file_id* is returned.

For new files, the appropriate file headers are also set up.

FORTRAN integer function hdfopen(filename, access, n dds)

character*(*) filename

integer access, n_dds

HEclear HDF Reference Manual

HEclear

VOID HEclear()

Purpose Clears all information on reported errors from the error stack.

Return value None.

 \boldsymbol{HEpush} creates an error stack. $\boldsymbol{HEclear}$ is then used to clear this stack after any errors are processed. Description

2-363 December 30, 2003

HEpush

VOID HEpush(int16 error_code, char *funct_name, char *file_name, intn line)

error_code IN: HDF error code corresponding to the error

funct_name IN: Name of function in which the error occurred

file_name IN: Name of file in which the error occurred

line IN: Line number in the file that error occurred

Purpose Pushes a new error onto the error stack.

Return value None.

Description HEpush pushes the file name, function name, line number, and generic

description of the error onto the error stack. **HEreport** can then be used to give

a more case-specific description of the error.

If the stack is full, the error is ignored. **HEpush** assumes that the character strings *funct_name* and *file_name* are in semi-permanent storage, so only

pointers to the strings are saved.

HDF Reference Manual HEreport

HEreport

VOID HEreport(char *format, ...)

format IN: Output string specification

Purpose Adds a text string to the description of the most-recently-reported error (only

one text string per error).

Return value None

Description HEpush places on the error stack the file name, function name, line number,

and a generic description of the error type. **HEreport** can then be used to give a more case-specific description of the error. Only one additional annotation

can be attached to each error report.

The format argument must conform to the string specification requirements of

printf.

HEvalue

int16 HEvalue(int32 level)

level IN: Level of the error stack to be returned

Returns an error from the specified level of the error stack. Purpose

Return value The error code if successful for DFE_NONE otherwise.

H Functions for Low-level Development

The following H functions are documented in the *Function Specifications* chapter of the *HDF Specification and Developer's Guide*. Note that the functions documented in that chapter include the following:

- Several H-level functions that are intended for low-level development and are not generally appropriate for application programming. The functions are documented only in the *HDF Specification and Developer's Guide*.
- Several more-broadly used H-level functions that are also documented in this reference manual.

HDF Definition List

3.1 Definition List Overview

This section of the Reference Manual contains a listing of all definitions used with HDF routines. The definitions are categorized by their name prefix (the portion of the name before the underscore) into tables. The tables themselves are alphebetized by name.

This section is primarily intended to be of use to Fortran programmers whose compilers do not support include files, and need to know the values of the definitions so that they can be explicitly defined in their programs.

TABLE 3A

*_INTERLACE - Interlace Mode Codes

Definition Name	Definition Value
FULL_INTERLACE	0
NO_INTERLACE	1

TABLE 3B

*_WILDCARD - Wildcard Code

	Definition Name	Definition Value
Ī	DFREF_WILDCARD	0

TABLE 3C

AN_* - Multifile Annotation Codes

Definition Name	Definition Value
AN_DATA_LABEL	0
AN_DATA_DESC	1
AN_FILE_LABEL	2
AN_FILE_DESC	3

TABLE 3D

COMP_* - Raster Image Compression Codes

Definition Name	Definition Value
COMP_NONE	0
COMP_RLE	11
COMP_IMCOMP	12
COMP_JPEG	2

TABLE 3E

COMP_CODE_* - General Compression Codes

Definition Name	Definition Value
COMP_CODE_NONE	0
COMP_CODE_RLE	1
COMP_CODE_NBIT	2
COMP_CODE_SKPHUFF	3
COMP_CODE_DEFLATE	4
COMP_CODE_INVALID	5

TABLE 3F

DF_* - Maximum Length Codes

Definition Name	Definition Value
DF_MAXFNLEN	256

TABLE 3G

DFACC_* - File Access Codes

Definition Name	Definition Value
DFACC_READ	1
DFACC_WRITE	2
DFACC_CREATE	4
DFACC_ALL	7
DFACC_RDONLY	1
DFACC_RDWR	3

TABLE 3H

DFE_* - Error Codes

Definition Name	Definition Value
DFE_NOERROR	0
DFE_NONE	0
DFE_FNF	1
DFE_DENIED	2
DFE_ALROPEN	3
DFE_TOOMANY	4
DFE_BADNAME	5
DFE_BADACC	6
DFE_BADOPEN	7
DFE_NOTOPEN	8
DFE_CANTCLOSE	9
DFE_READERROR	10
DFE_WRITEERROR	11
DFE_SEEKERROR	12
DFE_RDONLY	13
DFE_BADSEEK	14
DFE_PUTELEM	15
DFE_GETELEM	16
DFE_CANTLINK	17
DFE_CANTSYNC	18

DFE BADGROUP	19
DFE GROUPSETUP	20
DFE_PUTGROUP	21
DFE_GROUPWRITE	22
_	23
